

BMJ Open is committed to open peer review. As part of this commitment we make the peer review history of every article we publish publicly available.

When an article is published we post the peer reviewers' comments and the authors' responses online. We also post the versions of the paper that were used during peer review. These are the versions that the peer review comments apply to.

The versions of the paper that follow are the versions that were submitted during the peer review process. They are not the versions of record or the final published versions. They should not be cited or distributed as the published version of this manuscript.

BMJ Open is an open access journal and the full, final, typeset and author-corrected version of record of the manuscript is available on our site with no access controls, subscription charges or pay-per-view fees (<http://bmjopen.bmj.com>).

If you have any questions on BMJ Open's open peer review process please email [info.bmjopen@bmj.com](mailto:info.bmjopen@bmj.com)

**Abstract**

**Objectives:** Our objective was to review the literature on the inferred duration of the infectious period of COVID-19, caused by SARS-COV-2 virus, and provide an overview of the variation depending on the methodological approach.

**Design:** Rapid scoping review. Literature review with fixed search terms, up to 1<sup>st</sup> April 2020. Central tendency and variation of the parameter estimates for infectious period in (a) asymptomatic (b) symptomatic cases from (i) virological studies (repeated testing), (ii) tracing studies (iii) modelling studies were gathered. Narrative review of viral dynamics.

**Information sources:** Search strategies developed and the following searched: PubMed, Google Scholar, MedRxiv, BioRxiv. Additionally, the Health Information Quality Authority (Ireland) viral load synthesis was utilised, which screened literature from PubMed, Embase, ScienceDirect, NHS evidence, Cochrane, medRxiv and bioRxiv, HRB open databases.

**Results:** There was substantial variation in the estimates, and how infectious period was inferred. One study provided approximate median infectious period for asymptomatic cases of 6.5-9.5 days. Median pre-symptomatic infectious period across studies varied over <1-4 days. Estimated mean time from symptom onset to two negative RT-PCR tests was 13.4 days (95%CI: 10.9-15.8), but was shorter when studies included children or less severe cases. Estimated mean duration from symptom onset to hospital discharge or death (potential maximal infectious period) was 18.1 days (95%CI: 15.1–21.0); time to discharge was on average 4 days shorter than time-to-death. Viral dynamic data and model infectious parameters were often shorter than repeated diagnostic data.

**Conclusions:** There are limitations of inferring infectiousness from repeated diagnosis, viral loads, and viral replication data alone, and also potential patient recall bias relevant to estimating exposure and symptom onset times. Despite this, available data provides a preliminary evidence base to inform models of central tendency for key parameters, and variation for exploring parameter space and sensitivity analysis. Some current models may be underestimating infectious period.

**Strengths and limitations of this study**

- A comprehensive overview of the literature pertaining to inferred infectious duration of COVID-19, including indirect measures from virological, contact tracing, and modelling studies to 1<sup>st</sup> April 2020.
- Both narrative review and quantitative analysis presented

**Introduction**

Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), a new coronavirus, emerged in China in late 2019.[1,2] The virus causes COVID-19, a disease characterized by variable, mainly respiratory, symptoms across cohorts, from asymptomatic cases through to mild (for example, dry cough, fever) and severe cases (for example, pneumonia).[3,4] The severity of symptoms, and their clinical outcome, have been reported to vary by age-class and whether patients have underlying comorbidities. The case-fatality rate increases with age, and are highest for those above 70 years.[5,6] There are several cases of asymptomatic test-positive patients reported in the emerging literature (e.g. [4,7,8]). Furthermore, asymptomatic (and pre-symptomatic) cases have been shown to be infectious, and secondary cases have been reported.[9,10] However, the duration of this infectious period is difficult to measure accurately, and the time course of the natural history of infection generally must be inferred indirectly, via contact tracing of cases, serial repeated diagnostic virological studies, and/or through modelling approaches. Symptomatic cases can experience an infectious pre-symptomatic period before the onset of symptoms, therefore understanding the whole infectious period for this cohort requires estimating the duration of both periods. It is essential to rapidly gain insight into this key variable impacting our understanding of COVID-19 epidemiology. Anderson et al. [11] point out one of the “key unknowns” is the infectious period for COVID-19, which they suggest may be 10 days but subject to great uncertainty.

Here we gathered data from published research from peer-reviewed and preprints from 1<sup>st</sup> December to 1<sup>st</sup> April 2020, to characterize the variation in the infectious duration inferred from the three lines of evidence. We also provide a narrative review of the viral dynamic literature. Our focus was on duration, relative infectiousness has been dealt with elsewhere [12,13]

The aim of this review was to provide an overview and critical appraisal of published and preprint articles and reports that assess or quantify the inferred duration of the infectious period in order to best parameterise COVID-19 epidemiological transmission models.

## Materials and Methods

### *Conceptual model of population infection dynamics*

Infectious period was contextualised in relation to a working conceptual model of COVID-19 disease dynamics (Figure S1, supplementary material 1). From this conceptual model, three parameters were identified as important in context of this study:

T2, defined as: Duration of the total infectious period for asymptomatic cases, post-latent to recovery ['recover' in this context relates to clearing of infection]

T3, defined as: Duration of pre-symptomatic infectious period for those infected individuals who subsequently develop symptoms (that is, post-latent to onset of symptoms)

T5, defined as: Duration from onset of symptoms to recovery\* or death.

\* recovery was inferred as either the first of two clear RT-PCR tests, or hospital discharge after admission from COVID-19 related symptoms.

"Asymptomatic" case definition was interpreted pragmatically following Davies et al. [14,15], and may include very mild symptoms that may occur but are unnoticed.

T2, T3, T5 represent readily measurable parameters, but may be upper limits of infectious period, as patients may be non-infectious for a period before recovery or death. We also review evidence where infectiousness is inferred from viral shedding and contact tracing [transmission], see below.

### *Literature search*

A survey of the literature between 1<sup>st</sup> December 2019 and 1<sup>st</sup> April 2020 for all countries was implemented using the following search strategy. Publications on the electronic databases PubMed, Google Scholar, MedRxiv and BioRxiv were searched with the following keywords: "Novel coronavirus" OR "SARS-CoV-2" OR "2019-nCoV" OR "COVID-19" AND "infectious". Additionally, national and international government reports were monitored. No restrictions on language or publication status were imposed so long as an English abstract was available. Articles were evaluated for data relating to the aim of this review; all relevant publications were considered for possible inclusion. Bibliographies within these publications were also searched for additional resources.

Manual searches of the literature was undertaken using daily updated COVID19 collections from the National Centre for Biotechnology Information (NCBI) and MedRxiv servers (<https://connect.medrxiv.org/relate/content/181>), respectively, searching specifically for papers relating to "infectious period" or "infectious duration" from both empirical and modelling studies.

Finally, we utilised the complementary work undertaken by the Health Information and Quality Authority (HIQA) of Ireland, specifically the evidence summaries relating to asymptomatic transmission and viral load [16,17]. The protocol for the evidence synthesis is published on the HIQA website [18]. Briefly, the evidence synthesis process included searching databases from 30<sup>th</sup>

1  
2  
3 112 December 2019 to 27<sup>th</sup> March 2020 (PubMed, Embase, ScienceDirect, NHS evidence, Cochrane,  
4 113 medRxiv and bioRxiv, HRB open), screening, data extraction, critical appraisal and summarizing the  
5 114 evidence.

8  
9 115 Our aim was to have as great a breadth for an evidential base as possible, to clarify what evidence  
10 116 was available to inform on the infectious period of COVID19, and to identify key characteristics of  
11 117 the data sources and their interpretation. Therefore, our approach is a scoping review (following  
12 118 [19]). However, due to the emergent nature of COVID-19, this work is considered a rapid review.[20]  
13  
14 119 This paper follows the Preferred Reporting Items for Systematic Reviews and Meta-Analyses—  
15 120 Extension for Scoping Reviews (PRISMA-ScR) checklist.

19 121  
20  
21 122 Inclusion criteria were for papers that provided data to inform duration of infectious period based  
22 123 on: time from symptoms to recovery; time from symptoms to death; time from symptoms to  
23 124 diagnostic test clearance [ $\geq$ two clear tests, defined as at least two consecutive negative reverse  
24 125 transcriptase polymerase chain reaction (RT-PCR) tests conducted 24 hours apart]; pre-symptomatic  
25 126 infectious period; time from first diagnostic test to diagnostic test clearance [ $\geq$ two clear tests] for  
26 127 pre-symptomatic/asymptomatic cases. Inclusion criteria for viral dynamics, were papers which  
27 128 reported viral load via cycle threshold (Ct) values from RT-PCR testing over repeated sampling of  
28 129 infected patients, and studies that additional reported viral isolation.

30  
31 130 For quality control, studies were (i) selected and screened initially by three members of the team  
32 131 from search terms outlined above (ÁBC, KH, FB), with parameters identified and recorded. (ii) This  
33 132 was reviewed and supplemented by manual search by a different two team members (AWB, DM),  
34 133 again with parameters identified and recorded. (iii) Finally, the review was then internally reviewed  
35 134 by an additional two members of the team (CMc, MC), and cross-referenced with other parameter  
36 135 synthesis documents being worked on by the group (all authors).

37  
38 136 **Parameter comparison**

39  
40 137 Parameters of interest

- 41  
42 138 1. *A-priori* it was decided to harvest parameter estimates for (i) asymptomatic, and (ii)  
43 139 symptomatic cases. As the period of infectiousness can only be estimated indirectly,  
44 140 parameter estimates from the literature was gathered from three different methodological  
45 141 approaches: Virological studies tracking patients overtime undertaking serial testing, where  
46 142 infectious period was inferred from diagnostic testing history and/or by virus isolation.

2. Contact tracing studies where infectiousness is inferred by infector-infectee histories and/or clusters of infection.
3. Model parameters entered into mathematical models [priors] representing explicitly infectious periods, or model parameters estimated from mathematical models [posterior estimates] estimating explicitly infectious periods

### Visual and quantitative comparisons

To compare parameters visually, simulated distributions were estimated from the central tendencies and variation metrics described in the primary literature. To simulate data, 10,000 random variates were drawn from random number functions in Stata (ME, version 15.1; StataCorp. 2017. Stata Statistical Software: Release 15. College Station, TX: StataCorp LLC) [rnormal, rgamma]. Where possible, the distribution reported within the primary literature was used to represent the distribution (e.g. Gaussian, Gamma). Where distributional data could not be inferred, point estimates were presented.

There were adequate comparable data gathered on the duration of T5 (duration from onset of symptoms to death or recovery) from virological studies to employ a meta-analytic model. Many of the studies report different central tendency estimates, including mean and median. Methods of reporting variation across this central tendency included standard deviation, range, inter-quartile range. To facilitate meta-analysis, reported estimates from all studies were converted to the mean and standard deviations based on the formulae given in Wan et al. [21].

To obtain the standard deviations from 95%CI, the method outlined in the Cochrane handbook [22] was used:

$$SD: \sqrt{n}(\text{Upper limit of CI} - \text{Lower limit of CI})/3.92$$

Standard Error (SE) was calculated from Standard Deviation (SD) and sample size (n), using:

$$SE = SD/\sqrt{n}$$

Comparisons were made using the METAAN package in Stata 15, using the random-effects (DerSimonian-Laird) model.[23] This model assumes heterogeneity between the studies; that is, it assumes that the true effect can be different for each study. The model assumes that the individual-study true effects are distributed with a variance  $\tau^2$  around an overall true effect, but the model makes no assumptions about the form of the distribution of either the within-study or the between-

studies effects. Weightings were derived from the standard error [precision] around the estimate. Comparisons were presented as forest plots. Heterogeneity between studies was tested using Cochran’s Q; the magnitude of the heterogeneity was categorised using  $I^2$  as high (>75%), moderate (50-75%), or low (<50%).[24]

Variation in duration across T5 virological studies was compared using a random effects meta-regression model, using the METAREG command in Stata 15.1. The hypothesis that heterogeneity may be related to the inclusion of children or depending on symptom severity within the sample, was tested in separate univariate models. Severity was dichotomised (0/1) into studies that included patients described as having ‘mild’ or ‘mild-moderate’ symptoms, versus studies that included patients with ‘moderate-severe’ or ‘severe’ symptoms. Similarly, studies were categorised into having some samples from “children” (as reported in the paper), or wholly adult samples. These variables were then fitted as a dichotomous dummy predictor [independent]. The parameter estimates from the regression model was solved using restricted maximum likelihood (REML); additionally, p-values were estimated using a Monte Carlo model with 1000 permutation test.[25]

Raw patient-level data were available from three studies in relation to time from onset to hospital discharge or death (potentially inferring maximal T5 duration). To estimate the predicted mean and 95%CI duration across these studies, data were analysed using a Gaussian random effects model (using XTREG command, Stata 15), with study categories fitted as the RE. A linear regression model with ‘study’ fitted as a categorical dummy variable was used to estimate the difference between duration across study datasets. Code and data are provided in Supplementary Material 2 & 3.

**Viral dynamics**

A narrative comparison of reported viral dynamics from studies that undertook serial viral load estimates from patients over their period of observation was undertaken. Trends in the literature, strength and weaknesses were identified, and a conceptual model illustrated.

## Results

### *Parameter comparison*

Overall, 65 parameter estimates were harvested from 48 papers (Tables 1, 2, 3).

#### *Infectious period for asymptomatic cases (T2)*

The overall distributions and point estimates from studies for T2 are presented in Figure 1 and Table 1.

Two virological studies reported on infectious period based on serial diagnostic testing, for asymptomatic cases, were found to have informative data. One of these studies reported on only one asymptomatic case, with exposure to negative tests being 11 days (Zhou et al, 2020). This duration should be considered an over-estimate, given that a latent period is not taken into consideration. Hu et al. [7] tracked infections of close contacts to infected persons and considered patients asymptomatic at time of diagnosis. Infectious period was defined as time from diagnosis to the first of two clear tests, providing a median duration of 9.5 days (n=24) range: 1 – 21; 3.5-13.0 IQR.

Importantly, Hu et al. [7] found that the infectious period was different between those who subsequently exhibited symptoms (i.e. pre-symptomatic) and those who did not: The median duration for asymptomatic infectious was 6.0 days (IQR: 2.0 - 12.0; N=19). This was reduced to 4.0 days (2.0 - 15.0) for cases that were asymptomatic without abnormal computed tomography (CT) scans (n=7).

Two tracing studies provide informative data (Table 1; [7,8]). Infectious period was inferred indirectly from data provided in Ma et al. [8], whereby infectious period was estimated as the difference between the upper latent period estimate minus the serial interval. Ma et al. [8] reports on 49 asymptomatic cases and inferred serial interval from infector-infectee pairs. Serial interval was calculated by assuming “onset” was at first diagnosis. Hu et al. [7] reported on a case-study cluster of infection within a house where the primary case was asymptomatic. Secondary infections occurred 4-9 days after index case exposure, the index patient tested positive until day 29 post exposure.

Modelling studies that have attempted to fit differing parameters depending on the severity of symptoms have used differing nomenclature, for example asymptomatic, “mild” or subclinical cases (Table 1).[14,15,26,27] Two papers by Davies and colleagues [14,15] model this parameter as a

gamma distribution with a mean periods of 5-7 days (Fig. 2); importantly, these papers assume infectious period is the same for asymptomatic and symptomatic cases.

### Pre-symptomatic, infectious period (T3)

Pan et al. [3] and Hoehl et al. [28] describe the cases of two individuals tracked and serially tested by real-time reverse transcriptase polymerase chain reaction (RT-PCR) after being exposed to a patient with confirmed infection. In the latter study, the virus was isolated from samples, indicating transmission potential.

Four studies from China, Germany and Singapore provide informative data through tracing infections from cluster of infections, and through infector-infectee pairs (Table 2).[4,9,29,30] These papers included the study by Rothe et al. [9], which clarified that an asymptomatic patient visiting Germany from China may have actually experienced very mild symptoms around the time of transmission occurred (see discussion).

Five modelling papers incorporated pre-symptomatic infectious period reported as prior distributions or estimated as a model output. Two papers describe the prior distribution using a gamma distribution.[14,15] Tindale et al. [31] provide mean point estimates under four different scenarios (two populations, early and late epidemic period). Peak et al. [32] derives estimates of the pre-symptomatic infectious duration from a model of serial interval, and report scenarios where there are pre-symptomatic infectious periods.

The approximated distributions are simulated in Figure 2, which demonstrates the between-study heterogeneity in this parameter. The point estimates primarily cluster around the central tendencies of the distributions, except for Tindale et al. [31], for a model reporting for late occurring cases in Tianjin, China (8.2 days).

### Post-symptom onset, infectious period (T5)

The T5 parameter was informed from three lines of evidence from empirically driven studies:

- time from symptoms onset to the first of two clear RT-PCR tests
- time from symptoms to hospital discharge
- time from symptoms to death

Figure 3 presents the forest plot for the mean time from symptom onset to clearance, based on serial testing meta-analysis (n=15). The mean estimated duration was 13.4 days (95%CI: 10.9-15.8). There was high heterogeneity across studies (Cochrane's Q;  $p < 0.001$ ;  $I^2 > 75\%$ ). A random effects (RE) meta-regression model suggested significant variation depending on whether studies included

children as part of the sample (n=15 studies; Proportion of between-study variance explained Adj.  $R^2 = 43.8\%$ ). Overall, the model estimated studies including children had on average 5.8 days shorter duration than adult only studies (95%CI: 1.7-10.0; p=0.040; SE(p)=0.003). A second univariate RE meta-regression model suggested that there was non-significant increased mean duration of 4.0 days (95%CI: -0.6-8.6; p=0.111; SE(p)=0.005; Adj.  $R^2 = 22.0\%$ ; n=14) for studies that included moderate-severe or severe cases, relative to mild or mild-moderate severity cases.

High transmissibility during the first 5 days post symptom onset was described by Cheng et al. [33], based on secondary attack rates for 12 infector-infectee pairs. No contacts (n=1043) with primary cases were infected after five days of the index case onset of symptoms, inferred by the authors to suggest transmission occurring at symptom onset (but conceivably also suggest pre-symptomatic infection). Based on a cumulative density function, the authors suggest that infectiousness declines rapidly from onset of infection (distribution was truncated at 30 days); estimated cumulative infectiousness was 66.9% (95%CI: 28.7-94.8) by day 1, and reached 86.9% (95%CI: 64.3-99.5) by day 5 post-symptom onset (Figure S2).

For tracking studies relating to time to hospital discharge or death, raw case level data were available (studies n=3).[31,34–36] Histograms of the raw data are presented in Figure 4, along with the aggregated distribution. A random effect model suggested a mean duration of 18.1 days (95%ci: 15.1 – 21.0). However, there was significant variation across studies, with time to discharge being 4.96 days shorter (95%CI: 2.15- 7.76; [35]), or 3.79 days shorter (95%CI: 0.8-6.7; [31]), than time-to-death [34].

Two modelling papers use priors (mean: 3.2-3.5 days) to represent clinical infectious period.[14,15] However, the distribution for this parameter is right censored when patients are hospitalised or isolated and therefore not an estimate of the full infectious period *per se*.

#### Infectious period for symptomatic cases (T3+T5)

Two tracing studies supplied parameter estimates for the full infectious period for patients who develop symptoms. [8,29] He et al. [29] inferred from a publicly available dataset of 77 infector-infectee pairs that infectiousness began 2.3 days (95% CI, 0.8–3.0 days) prior to symptom onset, peaking at 0.7 days (95% CI, -0.2–2.0 days), and continued up to 7 days from onset. The authors suggest that the transmission risk diminishes 7 days post symptom onset. This suggests that the average infectious period, assuming a symptomatic infectious period of 7 days was approximately 9.3 days (7.8-10 days 95%CI, where CI is only reported for the pre-symptomatic period). He et al. [29] estimated that the proportion of all transmission that was pre-symptomatic was 44% (95% CI,

1  
2  
3 291 25–69%). Ma et al. [8] analysed data from a number of countries (China, Germany, Japan, Malaysia,  
4  
5 292 Singapore, Vietnam), collating 1155 cases from public data. They estimate several parameters,  
6  
7 293 including “maximum latent period” and the serial interval. The authors estimated the infectious  
8  
9 294 period as maximum latent period minus the serial interval. Given their parameter estimates and  
10  
11 295 methodological approach, infectious period would have been 5 days (range 0-24; IQR: 2-9;  
12  
13 296 calculated from data presented within the paper).  
14  
15 297 Seven modelling papers reported duration of infectious period ( $T_3+T_5$ ; Table 4), with the reported  
16  
17 298 central tendency for the distribution varying from 3-20 days. The form of the distribution offered to  
18  
19 299 models for this parameter varied considerably, including point estimates (deterministic models), flat  
20  
21 300 (uniform), Gaussian, Weibull and gamma distributions. Li et al. [27] estimated the shortest median  
22  
23 301 duration of 3.45 days, with a flat (uninformative) prior distribution corralled between 3-5 days. In  
24  
25 302 contrast, Zhu et al. [37] used a mean prior of 10 days, with the model estimated mean duration  
26  
27 303 being 12.5 days (variance 10; Weibull distribution). Piccolomini and Zama [38] used a fixed estimate  
28  
29 304 of 20 days infectious period, to model the Italian epidemic. Two papers from the same group [14,15]  
30  
31 305 suggested that infectious period for asymptomatic cases approximated for symptomatic cases where  
32  
33 306 there was no right censoring (that is, transmission being halted through isolation or hospitalisation;  
34  
35 307 gamma distributions of mean 5 or 7 days). Tuite et al. [26,39] also assumed the same duration for  
36  
37 308 “mild” and “severe” symptomatic cases (6-6.5 days).

### 310 ***Viral load dynamics***

311 Viral load was reported from 21 papers using real-time reverse transcriptase polymerase chain  
 312 reaction (rRT-PCR) testing, generally post-symptomatic monitoring.[3,29,40–59] Qualitatively, the  
 313 viral dynamics described early increase in viral load, peaking around onset or within 2-4 days of  
 314 symptom onset (Figure 5 for a theoretical model), before decreasing gradually over the next one to  
 315 three weeks post symptom onset. Maximum duration of detection ranged from approximately 20-49  
 316 days, with the longest duration associated with faecal samples (see below for discussion). The  
 317 duration where ribonucleic acid (RNA) was recoverable by RT-PCR may have been truncated due to  
 318 insufficient follow-up in some cases. Studies that have investigated blood samples have provided  
 319 some evidence for an association with severity of infection [16,60], though it is not clear whether  
 320 this is a consistent feature of SARS-CoV-2 infection [40].

321 It should be noted the lack of data on pre-symptomatic or asymptomatic cases with regards viral  
 322 load. An exception was Kam et al. [61] who describe a pre-symptomatic case in an infant. In another  
 323 study, Zou et al. [53] undertook serial RT-PCR testing from nasal and throat swab samples from 14  
 324 imported cases, and 4 secondary cases, in Guangdong, China. The dynamics of the infection in terms  
 325 of cycle threshold (Ct) values and RNA copy number were described; Ct values of 30.76, 27.67,  
 326 24.56, and 21.48 corresponding to  $1.5 \times 10^4$ ,  $1.5 \times 10^5$ ,  $1.5 \times 10^6$ , and  $1.5 \times 10^7$  copies per milliliter.  
 327 Hence, lower Ct values infer higher viral loads. The authors report on a patient without symptoms,  
 328 but with positive nasal swabs (Ct values, 22 to 28) and throat swabs (Ct values, 30 to 32) testing  
 329 positive on days 7, 10, and 11 after contact. Importantly, the authors suggest “the viral load that was  
 330 detected in the asymptomatic patient was similar to that in the symptomatic patients.”  
 331 Furthermore, Kimbell et al. [62] report that Ct values between asymptomatic (21.9 to 31.0), pre-  
 332 symptomatic (15.3 to 37.9), and symptomatic cases (18.6 to 29.2) within a nursing home  
 333 environment did not differ significantly. To et al. [59] present data on temporal profile of viral load  
 334 from saliva samples, and found that median initial and peak viral loads in severe cases were non-  
 335 significantly higher ( $p > 0.5$ ) by approximately 1 log<sub>10</sub> higher than those in mild cases. Liu et al. [58]  
 336 present data showing viral load being 60 times greater for severe cases relative to mild cases.

337 This lack of pre-symptomatic data may result in left truncation of the risk distribution associated  
 338 with viral load and shedding. Therefore, the typical timing of peak viral shedding (whether prior to,  
 339 at, or after onset), and its impact on transmission, is still uncertain. He et al. [29] reported highest  
 340 viral load at symptom onset from patients sampled in a hospital in China. Furthermore, the author’s  
 341 estimate using a separate infector-infectee dataset ( $n=77$ ) that 44% (95% CI: 25–69%) of infectee  
 342 cases were infected during the pre-symptomatic stage of the infector. Separately, a modelling paper

343 by Ferretti et al. [63] also appears to support this, estimating that 47% (0.9/2) of total transmission  
344 contributing  $R_0$ , an overall measure of transmission during an infection, was pre-symptomatic (also  
345 see [33]).

346 Wölfel et al. [50] provides important data on a cohort of nine ‘mild’ cases which were serially tested  
347 using sputum, swabs (throat and nasopharyngeal), urine and faecal samples over time. Importantly,  
348 the virus was isolated, and inferences on viral replication could be made. Viral Isolation, and insights  
349 into viral replication, improve inference around viral dynamics and transmission risk. The study  
350 suggested high viral loads shortly after symptom onset, which declined thereafter over time. Positive  
351 cultures were found from day 3-8 post-symptom onset (Figure S3), and the minimum 5% isolation  
352 success was achieved up to 9.8 (95% CI: 8.5-21.8) days post onset from throat and lung samples but  
353 not faeces, blood or urine.

## Discussion

Inferring infectiousness was challenging given the heterogeneity of evidence available. Virological diagnostic studies provide robust time series of infection, however, is limited by inferring the relationship between PCR diagnostics and infectiousness. These data can also be affected by sampling procedure and sample sites (e.g. upper respiratory, lower respiratory, faeces, urine, blood). We have excluded RT-PCR durations based on faecal sampling due to the uncertainty whether these data pertain to transmission potential ([50]; see below). Virological studies where culturing has taken place, and where viral replication can be inferred would also be considered superior data to infer infectious period, relative to estimates of viral load alone.[50] Where this has taken place, the data would suggest average infectious periods of up to 9.8 days post-symptoms. Recent modelling work suggest that the duration of viral detectability could overestimate the infectious period somewhere between 2-6 days.[64]

Viral load studies suggest peak viral load occurs close to symptom onset (potentially, -1 to 7 days of onset), however there is uncertainty whether this typically occurs prior to, on, or after onset (Figure 5 for conceptual model). High viral loads, measured as Ct values, have been recorded for one week to 20 days post symptom onset, with a general decreasing trend with time. For example, To et al. [59] estimates a declining slope per day for log<sub>10</sub> RNA copies per ml of -0.15 (95% CI -0.19 to -0.11;  $R^2=0.71$ ). There are some studies reporting associations between viral load and symptom severity, with higher metrics of viral load in severe cases.[3,58,59] However, Zou et al. [53], and more recent data from Italy,[64,65] suggest similar viral loads in symptomatic and asymptomatic cases.

We tested the hypothesis that severity of symptoms had an effect on symptomatic infectious duration using a meta-regression approach. There was a trend towards studies that included severe cases tended to have longer duration (estimated to be 4.0 days longer), but the effect was not significant. Some studies have reported an association between duration of infectiousness and severity (e.g. [58]). But uncertainty of whether this is robust remains.

Virological studies that included children (either mixed adult children, or children only cohorts) appeared to have shorter T5 durations (estimate: 5.8 days shorter). Liao et al. [66] present data which suggests that children and 'young adults' (<35 years old) infected cases exhibited long incubation time (exposure to symptom on-set; mean 7.2 days), and short serial interval (mean 6.5 days; median 1.9 days; time from onset in primary to onset in secondary case).

Contact tracing studies provided robust evidence of transmission events, and therefore infectiousness, but can be limited by the inferred timing of events, and symptoms experienced, due

1  
2  
3 386 to the self-reported nature of data collection (recall bias). The subjective nature of self-reporting  
4  
5 387 indeed can have an impact on case definitions of ‘asymptomatic’, which has led to some doubt on  
6  
7 388 asymptomatic transmission in one case.[9] Rothe et al. [9]describe a case of apparent asymptomatic  
8  
9 389 transmission from a Chinese visitor to business associates in Germany, which was cast into doubt  
10  
11 390 when health officials reported that the patient had indeed experienced some, albeit minor,  
12  
13 391 symptoms.[67] Rothe et al. [9] subsequently updated the clarification of the patients self-reported  
14  
15 392 symptoms during the presumed asymptomatic infectious period, which included “feeling warm” and  
16  
17 393 “feeling cold”. However, the patient only “recognized getting sick” after she returned to China on  
18  
19 394 day four after the presumed exposure event.

20  
21 395 Modelling parameters provide information on how COVID-19 data are being used and interpreted in  
22  
23 396 the research community, given the limited data available. Posterior estimates also provide  
24  
25 397 information on the parameter space at which infectious period central tendency reside, given other  
26  
27 398 parameters and assumptions in the model. Models used highly varied approaches to modelling  
28  
29 399 infectious period, which in turn resulted in highly variable parameter estimates used to inform the  
30  
31 400 studies.

32  
33 401 *Overall duration findings*

34  
35 402 There are few data for the precise definition of the asymptomatic infectious period (T2) parameter.  
36  
37 403 Some reported asymptomatic cases can actually be pre-symptomatic, when cases are subject to  
38  
39 404 follow-up (e.g.[66]; see discussion above). However, Hu et al. [7] do provide the data for  
40  
41 405 asymptomatic cases [that remain asymptomatic] across their presumed infectious period. Therefore,  
42  
43 406 in the first instance a parameter mimicking their data is probably the best available data. Note, there  
44  
45 407 is a large variation in this data parameter, and a gamma distribution of a shape alpha 3, beta 2, mean  
46  
47 408 6, may be appropriate for the initial model runs. Despite these being the primary informative data,  
48  
49 409 caution is required, given the uncertainty around the relationship between RT-PCR results and  
50  
51 410 infectiousness. Overall, an informed central tendency of ~6 days, with very low probability draws for  
52  
53 411 durations >20 days for the T2 parameter may be considered given the current state of knowledge.

54  
55 412 The pre-symptomatic period is sometimes referred to as ‘preclinical infectious’ period (parameter  
56  
57 413 T3). This has been estimated from several papers, and the central tendency of these estimates vary  
58  
59 414 from <1 - 4 days, cautiously approximating to 2 days, on average. The maximal reported period for  
60  
415 T3 from any population, was reported by Tindale et al. [31] at 8.2 days. Current models have used  
416  
417 central tendency estimates of 0.5 to 2.4 days.[14,15,26,39] It should be noted, that this period could  
418  
also be measured as the difference between incubation and latent period, or the difference between  
serial interval and incubation period.[12] The relative consistency around the duration of this period

allows for some confidence of its distribution. Current understanding of viral dynamics of infection suggest that viral load and shedding increases during post-latent phase, peaking around onset [for symptomatic cases], before declining.[29,50,53] This aspect of the natural history of infection may be important when attempting to model transmission dynamics.

Length of infectious period in symptomatic cases that do not isolate (T5 parameter) has also been rarely directly measured in the literature, as serial monitoring of patients in terms of symptoms or viral load (rt-PCR) generally occurs after diagnosis and/or after admission to hospital [from a modelling perspective, this means cases are censored as they are assumed to no longer contribute to transmission]. If natural progression of infection after diagnosis or hospital admission mimics the course of infection for those who do not isolate, the review of the literature describing time to two clear tests is informative. Symptom onset to serial testing clearance [assessed the time to first of two RT-PCR clear tests] averaged 13.4 days (95%CI: 10.9-15.8) from our meta-analysis. In the maximal case, where patients succumb or fully recover from infection, time from symptoms to death or discharge may be informative. Studies that collated such information suggest mean durations of 18.07 days (95%ci: 15.14 - 20.99), but with time to discharge being 4.96 days shorter (95%CI: 2.15-7.76) on average than time to death. These values may represent an over estimation of the infectious period; one study suggested that there was on average 2.5 days between end of infectiousness and 'removal' (recovery or death).[37]

Cheng et al. [33] provided evidence of transmissibility, based on attack rate from primary to secondary cases, at around symptom onset. The authors estimate cumulative infectiousness from onset, which suggests that 67% of total infectiousness potential occurs by the first day post-onset. Most of the total infectiousness occurs within 5 days (86.9%) post onset, with the remaining infectiousness potential (13.1%) being distributed up to day 30 (this truncation is an assumption by the authors). It is possible that pre-symptomatic transmission occurred during this study, but the authors do not estimate what proportion of transmissions occurred during a pre-symptomatic infectious period, or its potential duration.

A model by He et al. [29] is informative for overall symptomatic duration (T3+T5), using 77 infector-infectee pairs where COVID-19 transmission occurred in China. The study reported that infectiousness was apparent on average 2.5 days prior to symptoms, reached a peak in risk at 0.6 days before symptoms, and decline up until 7 days after onset (9.5 days total infectious period). The proportion of transmission before symptom onset (area under the curve) was estimated as 44% (95% CI, 25–69%), based on inferences on incubation period. The authors suggest their data supported the view that transmission risk decline substantially after 7 days post-symptoms onset.

1  
2  
3 452 Model estimates used for infectious period parameter appears to be shorter than virological studies  
4  
5 453 tracking RNA viral load over time. For example, Liu et al.[27] fitted a flat prior distribution for mean  
6  
7 454 duration ( $D$ ) fixed to vary between:  $2 \leq D \leq 5$  days, and Lavezzo et al. [64] fixed infectious period to 2  
8  
9 455 days in their epidemic model; whereas viral repeat testing studies provide evidence to suggest high  
10  
11 456 viral loads can be detected to up 20 days [e.g. pharyngeal swabs], and potentially longer from faecal  
12  
13 457 samples (up to 3-4 weeks post symptoms onset). Oral-faecal transmission risk is currently unknown,  
14  
15 458 but some doubt has been raised about studies that have reported positive RTPCR test results (see  
16  
17 459 [68]; but there may be some evidence of the risk amongst children; [69]). Wölfel et al. [50] has  
18  
19 460 produced an important study that provides some data on viral replication, and the site and duration  
20  
21 461 over which this may be taking place. Their data suggests that viral replication, with high viral loads,  
22  
23 462 occur in the upper respiratory tract, over the first week of symptoms peaking in day 4. Virus could  
24  
25 463 not be isolated from faecal samples, despite high RNA concentration. Furthermore, virus was not  
26  
27 464 isolated from blood or urine in that study.[50]

**Study limitations**

466 Overall, the studies included were of good quality, though due to the rapid need for information  
467 from the global research community many papers are pre-prints that have yet to be reviewed (at  
468 time of writing). Many papers were limited in terms of sample sizes, with several papers being case  
469 studies of one patient or single cluster outbreaks. There was a diversity of methods employed to  
470 infer dynamics of infectiousness across studies, and therefore the evidential base was variable. Some  
471 issues around nomenclature were noted, including definitions of asymptomatic, infectious period,  
472 latent, and incubation period. It is possible the same data may have been used across different  
473 studies, especially where publicly available data were used.

474 There was significant heterogeneity across study findings, and this was related to diversity of clinical  
475 findings and methods employed. The meta-analysis employed for one parameter (T5) using  
476 virological studies, where cross study comparisons could be made, suggested that the heterogeneity  
477 was high. Fu et al.[70] cautions against combining studies to give an overall estimate without  
478 exploring subgroup or meta-regression analysis, which we have done here. The meta-regression was  
479 based on a small number of studies ( $n=12-13$ ). Cochrane’s handbook suggests 10 studies for each  
480 level of a meta-regression, however in practice much lower numbers have been used to test  
481 hypotheses [22], as is the case here. Fu et al. [70] recommend a minimum of 4 studies per category,  
482 and therefore we dichotomised our predictor variables to ensure we met this minimum. Aggregating  
483 our categories resulted in crude findings.

Another limitation is that a systematic review was not undertaken to inform this research, hence there is a possibility that some relevant studies were overlooked. However, comprehensive search strategies were conducted by two independent research groups to inform this research, hence limiting the potential for missing key studies.

## Conclusion

There are few data to inform asymptomatic infectious period (T2 parameter). One study provide data that suggest a median period of 4-9.5 days, however, given the viral dynamics, this distribution could have an extended tail with low probability long infectious periods of up to 20 days. The pre-symptomatic infectious phase (T3) is quite narrowly defined to a mean of approximately 2 days (range: <1-4) within the literature. However, there is great uncertainty around the infectious period from onset to recovery or death (T5 parameter). The symptom onset until clearance (based on two negative RT-PCR tests) parameter estimate of 13.4 days (95%CI: 10.9-15.8) is informative for T5 parameter, only if one assumes that RT-PCR positive results equate to having infectious potential. Many current models corral the infectious period to shorter time periods than what virological studies have suggested, with one recent study suggesting that duration of viral detectability overestimates the infectious period on average by 2-6 days. While viral RNA can be detected for long periods of time, especially from faecal samples, the ability to isolate the virus from infected cases quickly declines after one-week post-symptoms. Some modelling papers have assumed that infectious period is invariant to whether cases are asymptomatic or symptomatic, however, the data available are not yet rich enough to inform whether this is a good assumption. Similarly, it is not yet established whether viral loads are similar between asymptomatic and mild, moderate, or severe symptomatic cases, with conflicting reports in the literature.

**Word count:** 5829

**Funding:** All investigators are full-time employees (or retired former employees) of University College Dublin, the Irish Department of Food and the Marine (DAFM), or the Irish Health Information and Quality Authority (HIQA). No additional funding was obtained for this research.

**Author contributions:** AWB conducted the eligibility screening of shortlisted studies, extracted the data and conducted the analyses with input from all authors; ÁC, KH and FB conducted the initial literature searches; DM, KOB, KW conducted searches and screened shortlisted studies; AWB completed the initial draft of the manuscript; CM reviewed the statistical methods; CM and MC undertook quality control interim review; All authors read and approved the final manuscript.

**Tables and figures**

**Figure 1:** Simulation of the parameter distribution inferred for duration infectious period for asymptomatic cases (T2) inferred infectious period for Davies et al. (2020a), grey/blue curve, Davies et al. (2020b) pink curve [model priors]. Green curve: Ma et al. (2020). Histogram is the distribution of asymptomatic cases to two clear tests reported by Hu et al. (2020). Reference lines are point estimates reported from Zhou et al. (2020), Li et al. (2020), and Tuite et al. (2020a & b).[7,8,14,15,26,27,39,71]

**Figure 2:** Simulation of the parameter distribution used for T3 (the duration of the pre-symptomatic infectious period for those infected individuals who subsequently develop symptoms). Curves represent simulated approximations of distributions, given information provided from primary literature. Vertical lines represent point estimates where distributions could not be inferred (see table 2). 1. Peak et al. [posterior]; 2. Davies et al. 2020b [prior]; 3. Rothe et al. 2020; 4. He et al. 2020; 5. Davies et al. 2020a [prior]; 6. Wei et al. 2020. [9,14,15,29,30,32]

**Figure 3:** Forest plot of the mean duration from onset of symptoms to death or recovery (T5) based on virological studies

**Figure 4:** Frequency distribution of **T5**, time from onset of symptoms to recovery (here hospital discharge or death), using patient level raw data from Kraemer et al. ([35,36]; pink bars), Linton et al. ([34]; purple bars) and Tindale et al. ([31]; green bars). Blue solid line is the kernel density of the aggregated dataset Dashed lines represent the mean and 95%CI from a random effects regression model.

**Figure 5:** Composite inferred model for cycle threshold (CT) value changes from serial RT-PCR testing for SARS-COV2; currently uncertain whether peak viral load typically occurs prior to, on, or post-symptom onset (primary literature informing this model includes [29,50,53,59]).

**Table 1:** Reported infectious period (IP) for asymptomatic cases (T5 parameter) from virological studies where serial diagnostic tests were undertaken to infer IP; tracking studies where IP is inferred from contact tracing; modelling studies where IP is reported as a prior (assumed parameter value) or an posterior estimate.

No.	Study	Countries	Parameter (days)	n	Central tendency reported	Variation (days; inclus.)	Comment
<b>Virological studies</b>							
[71]	Zhou et al. (2020)	China	11 days	1	Max		This study <b>serially swabbed and tested</b> symptomatic (17) and asymptomatic (1) cases via RTPCR. The single asymptomatic case tested positive up to 11 days post contact with an infected patient (presumed point of exposure).
[7]	Hu et al. (2020)	China	9.5 days	24	Median	1-21 range	<b>Serial testing.</b> Period between “onset” (where onset relates to first positive test) and clearance, adjudged via two negative RTPCR tests, deemed by the authors to be the ‘communicable period’. IQR: 3.5-13
<b>Tracking studies</b>							
[8]	Ma et al. (2020)	China, Germany, Japan, Singapore, South Korea, Malaysia, Vietnam	7.25 days*	49	Mean	5.91-8.69 (95%CI)	*Ma et al. (2020) does not report infectious period for asymptomatic cases explicitly within their paper. The authors estimated the infectious period as the upper estimated latent period minus the serial interval, using a dataset of 1155 cases from several countries (latent period was estimated with 11 infector-infectee pairs; serial interval was estimated from 689 infector-infectee pairs). Ma et al. (2020) reported a mean upper limit of latent period of 2.52 days; the mean serial interval for asymptomatic cases (using date of diagnosis for onset) was estimated to be 9.77 (94%CI: 8.43, 11.21).
[7]	Hu et al.	China		3		4-9	Cluster of infection within a

	(2020)					range	family, where the primary case was asymptomatic. The transmissions to secondary cases occurred over a period 4-9 days post the presumed point of exposure for the primary case.
<b>Modelling studies</b>							
[27]	Li et al. (2020)	China	3.5* [posterior from a model estimating duration for undocumented cases]		Median	3.19-3.78 95%CI	Li et al. (2020) do not explicitly attempt to model asymptomatic cases, or their infectious duration. Instead the population infected is divided into 'documented' and 'undocumented'. Documented were all cases where patients had symptoms severe enough to be confirmed infected; all other cases were considered undocumented. Therefore, this estimate represents asymptomatic and 'mild' cases. The 95%CI around the median infectious period estimate was 3.19-3.78
[26,39]	Tuite et al. (2020a &b)	Canada	6-6.5 [Prior]		[Fixed parameter within a deterministic model]		Mathematical model [deterministic], with a fixed parameter estimate of 6 or 6.5 days. Important to note that duration for 'mild' was equal to severe cases.
[14]	Davies et al. (2020) (a)	UK	7 days [Prior]		Mean		Model with asymptomatic infection compartment. Modelled with a gamma distribution, beta 1.4; alpha 5. Despite, the subclinical aspect of this parameter, it could be considered analogous to total infectious period without intervention.
[15]	Davies et al. (2020) (b)	UK	5 days [Prior]		Mean		Model with asymptomatic infection compartment. Modelled with a gamma distribution, k=4. Authors: "Assumed to be the same duration as total infectious period for clinical cases, including preclinical transmission"

**Table 2:** Reported infectious period (IP) for pre-symptomatic cases (T3 parameter) from virological studies where serial diagnostic tests were undertaken to infer IP; tracking studies where IP is inferred from contact tracing; modelling studies where IP is reported as a prior (assumed parameter value) or an posterior estimate.

	Study	Location	Parameter (days)	Central tendency reported	Variation (days; inclus.)	Comment
<b><i>Virological studies</i></b>						
[3]	Pan et al. (2020)	Beijing, China	1	Median		Case study of two individuals tracked due to exposure to an infected patient was <b>serially tested</b> prior to onset of symptoms.
[28]	Hoehl et al. (2020)	Flight from Wuhan to Germany	1	Median		Case study of <b>serially tested</b> at risk cohort flying from Wuhan to Germany. Two patients were asymptomatic test positive; additionally virus isolation was achieved, indicating potential infectiousness.
<b><i>Tracking studies</i></b>						
[4]	Huang et al. (2020)	Nanjing, China	4	Median	3-5 range	Follow-up <b>tracing</b> case study cluster of infection within a family demonstrating pre-symptomatic infection (n=10)
[9]	Rothe et al. (2020)	Germany	2	Median	1-3 range	<b>Tracing</b> case study of a cluster of infections whereby pre-symptomatic transmission occurred (n=3).
[29]	He et al. (2020)	Vietnam, Malaysia, Japan, China, Taiwan, USA, Singapore	2.3	Mean	95% CI, 0.8–3.0	<b>Tracing</b> paper infector-infectee pairs. Estimated from serial interval and incubation periods. N=77
[30]	Wei et al. (2020)	Singapore	2.5	Median	2-3 (IQR)	<b>Tracing</b> study investigating pre-symptomatic infections from primary cases to secondary cases in 7 clusters. N=8 primary cases. T3 estimated as the min. days between transmission period (TP) and primary case

						symptom onset, when TP straddled >1 day. Range: 2-6 days.
	<b>Modelling studies</b>					
[32]	Peak et al. (2020)	Massachusetts	0.8 [estimate]	Mean	-0.29-1.98 95% CI*	<b>Modelling paper</b> estimated under two scenarios – a serial interval of 4.8 days or 7.5 days. Under scenario one, the model estimated a period of pre-symptomatic transmission (median: 0.71). * the lower range was fixed at zero as the model allowed for no pre-symptomatic infectious case.
[37]	Zhu et al. (2020)	Wuhan, China	1.0 [estimate]	Mean		<b>Modelling paper.</b> Model estimated point value – This is a model derived value
[14]	Davies et al. (2020) (a)	UK	2.4 [prior]	Mean		<b>Modelling paper.</b> Gamma distribution; k=5.
[15]	Davies et al. (2020) (b)	UK	1.5 [prior]	Mean		<b>Modelling paper.</b> Gamma distribution: k=4
[26,39]	Tuite et al. (2020a & b)	Canada	0.5, 1 [prior]	Fixed		<b>Modelling paper.</b> Fixed parameter within a deterministic model.
[72]	Ferguson et al. (2020)	UK	0.5 [prior]	Fixed		<b>Modelling paper.</b> Fixed parameter within a this model, whereby infectiousness was assumed to begin 12 hours become symptoms.
[31]	Tindale et al. (2020)	Tianjin, China, and Singapore	2.9-2.6 [estimate]	Mean	1.2-8.2 mean range, depending on early or late cases, or whether in Tianjin, Singapore	Statistical <b>modelling</b> study estimating period pre-symptomatic transmission inferred from estimates of serial interval and incubation periods for populations in Tianjin and Singapore (n=228).

772

773

**Table 3:** Reported infectious period (IP) for post-symptomatic cases (T5 parameter) from virological studies where serial diagnostic tests were undertaken to infer IP [onset to  $\geq 2$  tests]; tracking studies where IP is inferred from patient histories from onset to recovery or death; modelling studies where IP is reported as a prior (assumed parameter value) or an posterior estimate.

No.	Study	Location	Parameter (days)	Central tendency reported	Variation (days; inclus.)	Comment
<b>Virological studies</b>						
[73]	Cai et al. 2020 (a)	China	12	Median	6-22 range	<b>Serial testing</b> study of n=10 mild cases RT-PCR confirmed in children. IQR: 8-15 days
[74]	Cai et al. 2020 (b)	China	14	Median	9-19 (IQR)	<b>Serial testing</b> study with n=298 confirmed (RT-PCR) cases treated within hospital setting
[75]	Chen et al.(2020)	China	12	Max.		Single case study for a patient admitted to hospital where RT-PCR <b>serial testing</b> was undertaken. Patient had an additional positive test at day 17, but subsequently tested negative
[76]	Cheng et al. (2020)	China	21	Max.		Case study of single patient <b>serially tested</b> by RT-PCR
[7]	Hu et al. (2020)	China	12	Median	12-14 (IQR)	<b>Serial testing</b> study of patients who were first tested (qRT-PCR) when asymptomatic; this subset subsequently developed symptoms (n=5).
[42]	Kim et al. (2020)	Korea	15.5	Median	14-17 (range)	<b>Serial testing</b> of two confirmed cases via RT-PCR. Viral load highest during early phase of infection (day 3-5).
[43]	Kujawski et al. (2020)	USA	26	Max.		<b>Serial testing</b> of two confirmed cases via RT-PCR. Mild to moderate symptoms.
[77]	Lee et al. (2020)	Taiwan	20	Max.		<b>Serial testing</b> (RT-PCR) of a single patient hospitalised presenting with pneumonia
[44]	Lim et al. (2020)	South Korea	16	Max.		<b>Serial testing</b> (RT-PCR) of a single patient hospitalised presenting with pneumonia. Two clear tests day 11, virus

						detectable again up to day 16.
[78]	Ling et al. (2020)	China	9.5	Median	2-22 (range)	<b>Serial testing</b> of two confirmed cases via RT-PCR. n=66. IQR: 6-11 days, oropharyngeal sampling. Mix of adult and children.
[79]	Liu et al. (2020)	China	11	Median	7-18 range	<b>Serial testing</b> of two confirmed cases via RT-PCR. n=10. 10-13 (IQR); adults, mild, moderate, and severe cases.
[45]	Marchand-Senéca et al. (2020)	Canada	23	Max		<b>Serial testing</b> (RT-PCR) of a single patient hospitalised presenting with pneumonia.
[3]	Pan et al. (2020)	China	10	Median	8-12 range	<b>Serial testing</b> (RT-PCR) of two patients hospitalised. Viral loads peaked days 5-6 post-onset.
[80]	Qu et al. (2020)	China	22	Max		<b>Serial testing</b> (RT-PCR) of a single patient hospitalised
[46]	Tan et al. (2020)	Vietnam	16	Max		<b>Serial testing</b> (RT-PCR) of a single patient hospitalised; throat sample.
[47]	Thevarajan et al. (2020)	Australia	7	Max		<b>Serial testing</b> (RT-PCR) of a single patient hospitalised; throat sample. Highest viral load on first test at day 4 in nasopharyngeal; day 6 for sputum.
[69]	Xing et al. (2020)	China	14	Median		<b>Serial testing</b> (RT-PCR) of a three (children) patients hospitalised. Mild-moderate infecting. Positive viral samples from faeces up to 4 weeks post-symptoms.
[52]	Young et al. (2020)	Singapore	12.5	Median		<b>Serial testing</b> (RT-PCR) of 18 patients hospitalised. Adults. Viral load peaked over testing series at day 4 since onset.
[81]	Yuan et al. (2020)	China	6	Median	4-10 (IQR)	<b>Serial testing</b> (RT-PCR) of 25 patients hospitalised. Children and adults. "Non-severe" cases.
[71]	Zhou et al. (2020)	China	20	Median	16-23 IQR	<b>Serial testing</b> (RT-PCR) of 191 patients hospitalised in two hospitals. Adults. 54 died. Survivors (n=137); Median (IQR) 20.0 days (17.0–24.0); Non-survivors

						(n=54); Median (IQR) 18.5 days (15.0–22.0); Shedding continued until death. Inferred shedding period; 8–37 days.
[82]	Chen J. et al. (2020)	China	11	Median	10–12 (95%CI)	<b>Serial testing</b> (RT-PCR) of 242 patients hospitalised. Adults. 90% mild/asymptomatic; 10% severe/critical.
[60]	Fang et al. (2020)	China	15.7	Mean	6.7 (sd)	<b>Serial testing</b> (RT-PCR) of 24 non-ICU patients hospitalised. Adults. Nasal samples.
[60]	Fang et al. (2020)	China	22.3	Mean	3.6 (sd)	<b>Serial testing</b> (RT-PCR) of 8 ICU patients hospitalised. Adults. Nasal samples.
[57]	Hill et al. (2020)	Scotland	9	Max.		<b>Serial testing</b> (RT-PCR) of a single patient (adult) hospitalised; nasal sample [throat sample: 6 days]. Mild.
[83]	Le et al. (2020)	Vietnam	12	Max.		<b>Serial testing</b> (RT-PCR) of a single patient (infant) hospitalised. Mild.
[58]	Liu et al. (2020)	China	10	Max.		<b>Serial testing</b> (RT-PCR) of a patients hospitalised. Adults. Mixed Mild/severe cases. N=76. 90% “early viral clearance” within 10days
[84]	Qiu et al. (2020)	China	10	Mean	7–22 range	<b>Serial testing</b> (RT-PCR) of a patients hospitalised. Children. N=36. Mild and moderate cases.
[59]	To et al. (2020)	Hong Kong	25	Max.		<b>Serial testing</b> (RT-PCR) of a patients hospitalised. N=7. Seven patients reported viral detection >20 days; viral load peaked during first week post-onset of symptoms.
[85]	Wu et al.	China	16.1	Mean	6.7 (sd)	<b>Serial testing</b> (RT-PCR) of patients hospitalised. Adults. N=74. Severe and non-severe cases.
<b>Tracking studies</b>						
[31]	Tindale et al. (2020)	Singapore	18	Median	9–33 range	Time from onset to discharge; range 9–33; n=53
[35,36]	Kraemer et al. (2020a);	Various	19	Median	3–37 range	Time from onset to discharge; Range: 3–37;

	[later published as: Xu et al. 2020]					n=70
[34]	Linton et al. (2020)	Wuhan, China	13	Median	6-41 range	Time from onset to death; range 6-41
[35,36]	Kraemer et al. (2020b)	Japan and China	19.25	Mean	12-24 range	Time from onset to death; n=4
[49,50]	Wölfel et al. (2020)	Germany	3-8 days	absolute	3-8 range	Tracked infection in mild cases in Germany, undertaking viral isolation studies to assess active replication across a number of samples sites (upper respiratory tract, blood, urine, faeces) over the duration of infection. 5% isolation success was achieved up to 9.78 (95% CI: 8.45-21.78) days post onset; n=9

778

779

**Table 4:** Reported infectious period (IP) for symptomatic cases (T3+T5 parameter) from virological studies where serial diagnostic tests were undertaken to infer IP [exposure to  $\geq 2$  tests]; tracking studies where IP is inferred from patient histories from onset to recovery or death; modelling studies where IP is reported as a prior (assumed parameter value) or an posterior estimate.

No.	Study	Location	Parameter (days)	Central tendency reported	Variation (days; inclus.)	Comment
<b>Tracking studies</b>						
[29]	He et al. (2020)	Vietnam, Malaysia, Japan, China, Taiwan, USA, Singapore	9.3 days	Mean	7.8-10 (95%CI*)	The paper reported on 77 infector-infectee pairs which were sequential/serially tested, using publicly available data. Viral dynamics (Guangzhou, China; N=94) interpreted by the authors suggested an infectious period starting 2.3 (95% CI, 0.8–3.0 days) days prior to symptoms, peaking 0.7 days (95% CI, –0.2–2.0 days), continuing up to 7 days from onset. * CI from pre-symptom infectious period only.
[8]	Ma et al. (2020)	Various	~5 days	Median	Range 0-24	The authors estimated the infectious period as latent minus the serial interval, using a dataset of 1155 cases. Range 0-24; IQR: 2-9; calculated from data presented within the paper.
<b>Modelling studies</b>						
[27]	Li et al. (2020)	China	3.45 days [posterior estimated from model for documented cases]	median	95%CI for the mean: 3.19, 3.72	Mathematical model. Priors for <u>mean</u> documented infectious period was a flat [uniform] distribution 2-5. 'Documented' cases were defined as those severe enough to be confirmed. This corraling of the infectious period relative to other

						studies should take into account that the distribution is used for the central tendency, not the whole distribution.
[26,39]	Tuite et al. (a, b) (2020)	Canada	6-6.5 days [prior; fixed parameter within a deterministic model]	Fixed parameter		Mathematical model [deterministic], with a fixed parameter estimate of 6.5 days (a) and 6 days (b), respectively. Important to note that duration for 'mild' was equal to severe cases.
[86]	Lourenco et al. (2020)	UK	~3-5 days [posterior; approximate depending on scenario tested]	mean	95%ci of 3-6 days	Mathematical model. The prior used was given a Gaussian distribution (normal curve); mean 4.5; SD 1; approximate 95%ci of 3-6 days. The reported posterior of this parameter was presented graphically and depended on R0 and proportion at risk. Depending on the scenarios tested, mean duration of infectiousness appeared to vary from 3-5 days.
[37]	Zhu et al. (2020)	Wuhan, China	12.5 days [posterior estimated from model]	Mean	11.4 variance	Mathematical model. The parameter was estimated using a Weibull distribution. The prior for this parameter was 10 days. The posterior variance around the mean was 11.4, and therefore the distribution had a long tail. This study was a modelling [SEIR extended model].
[15]	Davies et al. (b) (2020)	UK	7 days [Prior]	Mean		Model with asymptomatic infection compartment. Modelled with a

						gamma distribution, beta 1.4; alpha 5. Despite, the subclinical aspect of this parameter, it could be considered analogous to total infectious period without intervention.
[14]	Davies et al. (b) (2020)	UK	5 days [Prior]	Mean		Model with asymptomatic infection compartment. Modelled with a gamma distribution, k=4. Authors: "Assumed to be the same duration as total infectious period for clinical cases, including preclinical transmission"
[38]	Piccolomini and Zama (2020)	Italy	20 days [Prior]	Fixed		Parameter estimate assumed for the infectious period within an SEIRD model, fitted to data from the epidemic in Italy.

## Preferred Reporting Items for Systematic reviews and Meta-Analyses extension for Scoping Reviews (PRISMA-ScR) Checklist

SECTION	ITEM	PRISMA-ScR CHECKLIST ITEM	REPORTED ON PAGE #
<b>TITLE</b>			
Title	1	Identify the report as a scoping review.	1
<b>ABSTRACT</b>			
Structured summary	2	Provide a structured summary that includes (as applicable): background, objectives, eligibility criteria, sources of evidence, charting methods, results, and conclusions that relate to the review questions and objectives.	2
<b>INTRODUCTION</b>			
Rationale	3	Describe the rationale for the review in the context of what is already known. Explain why the review questions/objectives lend themselves to a scoping review approach.	3
Objectives	4	Provide an explicit statement of the questions and objectives being addressed with reference to their key elements (e.g., population or participants, concepts, and context) or other relevant key elements used to conceptualize the review questions and/or objectives.	3
<b>METHODS</b>			
Protocol and registration	5	Indicate whether a review protocol exists; state if and where it can be accessed (e.g., a Web address); and if available, provide registration information, including the registration number.	4-5
Eligibility criteria	6	Specify characteristics of the sources of evidence used as eligibility criteria (e.g., years considered, language, and publication status), and provide a rationale.	5
Information sources*	7	Describe all information sources in the search (e.g., databases with dates of coverage and contact with authors to identify additional sources), as well as the date the most recent search was executed.	4-5
Search	8	Present the full electronic search strategy for at least 1 database, including any limits used, such that it could be repeated.	4-5
Selection of sources of evidence†	9	State the process for selecting sources of evidence (i.e., screening and eligibility) included in the scoping review.	4-5
Data charting process‡	10	Describe the methods of charting data from the included sources of evidence (e.g., calibrated forms or forms that have been tested by the team before their use, and whether data charting was done independently or in duplicate) and any processes for obtaining and confirming data from investigators.	4-5
Data items	11	List and define all variables for which data were sought and any assumptions and simplifications made.	5-7
Critical appraisal of individual sources of evidence§	12	If done, provide a rationale for conducting a critical appraisal of included sources of evidence; describe the methods used and how this information was used in any data synthesis (if appropriate).	5-7
Synthesis of results	13	Describe the methods of handling and summarizing the data that were charted.	5-7

SECTION	ITEM	PRISMA-ScR CHECKLIST ITEM	REPORTED ON PAGE #
<b>RESULTS</b>			
Selection of sources of evidence	14	Give numbers of sources of evidence screened, assessed for eligibility, and included in the review, with reasons for exclusions at each stage, ideally using a flow diagram.	8, Tables 1-3
Characteristics of sources of evidence	15	For each source of evidence, present characteristics for which data were charted and provide the citations.	Tables 1-3
Critical appraisal within sources of evidence	16	If done, present data on critical appraisal of included sources of evidence (see item 12).	Tables 1-3
Results of individual sources of evidence	17	For each included source of evidence, present the relevant data that were charted that relate to the review questions and objectives.	8-13
Synthesis of results	18	Summarize and/or present the charting results as they relate to the review questions and objectives.	8-13; figures 1-5
<b>DISCUSSION</b>			
Summary of evidence	19	Summarize the main results (including an overview of concepts, themes, and types of evidence available), link to the review questions and objectives, and consider the relevance to key groups.	14-17
Limitations	20	Discuss the limitations of the scoping review process.	17-18
Conclusions	21	Provide a general interpretation of the results with respect to the review questions and objectives, as well as potential implications and/or next steps.	18
<b>FUNDING</b>			
Funding	22	Describe sources of funding for the included sources of evidence, as well as sources of funding for the scoping review. Describe the role of the funders of the scoping review.	18

JBI = Joanna Briggs Institute; PRISMA-ScR = Preferred Reporting Items for Systematic reviews and Meta-Analyses extension for Scoping Reviews.

\* Where *sources of evidence* (see second footnote) are compiled from, such as bibliographic databases, social media platforms, and Web sites.

† A more inclusive/heterogeneous term used to account for the different types of evidence or data sources (e.g., quantitative and/or qualitative research, expert opinion, and policy documents) that may be eligible in a scoping review as opposed to only studies. This is not to be confused with *information sources* (see first footnote).

‡ The frameworks by Arksey and O'Malley (6) and Levac and colleagues (7) and the JBI guidance (4, 5) refer to the process of data extraction in a scoping review as data charting.

§ The process of systematically examining research evidence to assess its validity, results, and relevance before using it to inform a decision. This term is used for items 12 and 19 instead of "risk of bias" (which is more applicable to systematic reviews of interventions) to include and acknowledge the various sources of evidence that may be used in a scoping review (e.g., quantitative and/or qualitative research, expert opinion, and policy document).

## Abstract

**Objectives:** Our objective was to review the literature on the inferred duration of the infectious period of COVID-19, caused by SARS-COV-2 virus, and provide an overview of the variation depending on the methodological approach.

**Design:** Rapid scoping review. Literature review with fixed search terms, up to 1<sup>st</sup> April 2020. Central tendency and variation of the parameter estimates for infectious period in (a) asymptomatic (b) symptomatic cases from (i) virological studies (repeated testing), (ii) tracing studies (iii) modelling studies were gathered. Narrative review of viral dynamics.

**Information sources:** Search strategies developed and the following searched: PubMed, Google Scholar, MedRxiv, BioRxiv. Additionally, the Health Information Quality Authority (Ireland) viral load synthesis was utilised, which screened literature from PubMed, Embase, ScienceDirect, NHS evidence, Cochrane, medRxiv and bioRxiv, HRB open databases.

**Results:** There was substantial variation in the estimates, and how infectious period was inferred. One study provided approximate median infectious period for asymptomatic cases of 6.5-9.5 days. Median pre-symptomatic infectious period across studies varied over <1-4 days. Estimated mean time from symptom onset to two negative RT-PCR tests was 13.4 days (95%CI: 10.9-15.8), but was shorter when studies included children or less severe cases. Estimated mean duration from symptom onset to hospital discharge or death (potential maximal infectious period) was 18.1 days (95%CI: 15.1–21.0); time to discharge was on average 4 days shorter than time-to-death. Viral dynamic data and model infectious parameters were often shorter than repeated diagnostic data.

**Conclusions:** There are limitations of inferring infectiousness from repeated diagnosis, viral loads, and viral replication data alone, and also potential patient recall bias relevant to estimating exposure and symptom onset times. Despite this, available data provides a preliminary evidence base to inform models of central tendency for key parameters, and variation for exploring parameter space and sensitivity analysis.

## Strengths and limitations of this study

- A comprehensive overview of the literature pertaining to inferred infectious duration of COVID-19, including indirect measures from virological, contact tracing, and modelling studies to 1<sup>st</sup> April 2020.
- Both narrative review and quantitative analysis presented

- 50 • Small number of comparable parameter estimates for meta-analysis is a limitation
- 51 • Much of the current research material on COVID-19 is from preprint papers, and therefore
- 52 have not gone through formal peer review

## 53 Introduction

54 Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), a new coronavirus, emerged in  
55 China in late 2019.[1,2] The virus causes COVID-19, a disease characterized by variable, mainly  
56 respiratory, symptoms across cohorts, from asymptomatic cases through to mild (for example, dry  
57 cough, fever) and severe cases (for example, pneumonia).[3,4] The severity of symptoms, and their  
58 clinical outcome, have been reported to vary by age-class and whether patients have underlying  
59 comorbidities. The case-fatality rate increases with age, and are highest for those above 70  
60 years.[5,6] There are several cases of asymptomatic test-positive patients reported in the emerging  
61 literature (e.g. [4,7,8]). Furthermore, asymptomatic (and pre-symptomatic) cases have been shown  
62 to be infectious, and secondary cases have been reported.[9,10] However, the duration of this  
63 infectious period is difficult to measure accurately, and the time course of the natural history of  
64 infection generally must be inferred indirectly, via contact tracing of cases, serial repeated diagnostic  
65 virological studies, and/or through modelling approaches. Symptomatic cases can experience an  
66 infectious pre-symptomatic period before the onset of symptoms, therefore understanding the  
67 whole infectious period for this cohort requires estimating the duration of both periods. It is  
68 essential to rapidly gain insight into this key variable impacting our understanding of COVID-19  
69 epidemiology. Anderson et al. [11] point out one of the “key unknowns” is the infectious period for  
70 COVID-19, which they suggest may be 10 days but subject to great uncertainty.

71 Here we gathered data from published research from peer-reviewed and preprints from 1<sup>st</sup>  
72 December to 1<sup>st</sup> April 2020, to characterize the variation in the infectious duration inferred from the  
73 three lines of evidence. We also provide a narrative review of the viral dynamic literature. Our focus  
74 was on duration, relative infectiousness has been dealt with elsewhere [12,13]

75 The aim of this review was to provide an overview and critical appraisal of published and preprint  
76 articles and reports that assess or quantify the inferred duration of the infectious period in order to  
77 best parameterise COVID-19 epidemiological transmission models.

**Materials and Methods**

***Conceptual model of population infection dynamics***

Infectious period was contextualised in relation to a working conceptual model of COVID-19 disease dynamics (Figure S1, supplementary material 1). From this conceptual model, three parameters were identified as important in context of this study:

T2, defined as: Duration of the total infectious period for asymptomatic cases, post-latent to recovery [‘recover’ in this context relates to clearing of infection]

T3, defined as: Duration of pre-symptomatic infectious period for those infected individuals who subsequently develop symptoms (that is, post-latent to onset of symptoms)

T5, defined as: Duration from onset of symptoms to recovery\* or death.

\* recovery was inferred as either the first of two clear RT-PCR tests, or hospital discharge after admission from COVID-19 related symptoms.

“Asymptomatic” case definition was interpreted pragmatically following Davies et al. [14,15], and may include very mild symptoms that may occur but are unnoticed.

T2, T3, T5 represent readily measurable parameters, but may be upper limits of infectious period, as patients may be non-infectious for a period before recovery or death. We also review evidence where infectiousness is inferred from viral shedding and contract tracing [transmission], see below.

***Literature search***

A survey of the literature between 1<sup>st</sup> December 2019 and 1<sup>st</sup> April 2020 for all countries was implemented using the following search strategy. Publications on the electronic databases PubMed, Google Scholar, MedRxiv and BioRxiv were searched with the following keywords: “Novel coronavirus” OR “SARS-CoV-2” OR “2019-nCoV” OR “COVID-19” AND “infectious”. Additionally, national and international government reports were monitored. No restrictions on language or publication status were imposed so long as an English abstract was available. Articles were evaluated for data relating to the aim of this review; all relevant publications were considered for possible inclusion. Bibliographies within these publications were also searched for additional resources.

Manual searches of the literature was undertaken using daily updated COVID19 collections from the National Centre for Biotechnology Information (NCBI) and MedRxiv servers (<https://connect.medrxiv.org/relate/content/181>), respectively, searching specifically for papers relating to “infectious period” or “infectious duration” from both empirical and modelling studies.

Finally, we utilised the complementary work undertaken by the Health Information and Quality Authority (HIQA) of Ireland, specifically the evidence summaries relating to asymptomatic transmission and viral load [16,17]. The protocol for the evidence synthesis is published on the HIQA website [18]. Briefly, the evidence synthesis process included searching databases from 30<sup>th</sup>

December 2019 to 27<sup>th</sup> March 2020 (PubMed, Embase, ScienceDirect, NHS evidence, Cochrane, medRxiv and bioRxiv, HRB open), screening, data extraction, critical appraisal and summarizing the evidence.

Our aim was to have as great a breadth for an evidential base as possible, to clarify what evidence was available to inform on the infectious period of COVID19, and to identify key characteristics of the data sources and their interpretation. Therefore, our approach is a scoping review (following [19]). However, due to the emergent nature of COVID-19, this work is considered a rapid review.[20] This paper follows the Preferred Reporting Items for Systematic Reviews and Meta-Analyses—Extension for Scoping Reviews (PRISMA-ScR) checklist.

Inclusion criteria were for papers that provided data to inform duration of infectious period based on: time from symptoms to recovery; time from symptoms to death; time from symptoms to diagnostic test clearance [ $\geq$ two clear tests, defined as at least two consecutive negative reverse transcriptase polymerase chain reaction (RT-PCR) tests conducted 24 hours apart]; pre-symptomatic infectious period; time from first diagnostic test to diagnostic test clearance [ $\geq$ two clear tests] for pre-symptomatic/asymptomatic cases. Inclusion criteria for viral dynamics, were papers which reported viral load via cycle threshold (Ct) values from RT-PCR testing over repeated sampling of infected patients, and studies that additional reported viral isolation.

For quality control, studies were (i) selected and screened initially by three members of the team from search terms outlined above (*ABC, KH, FB*), with parameters identified and recorded. (ii) This was reviewed and supplemented by manual search by a different two team members (*AWB, DM*), again with parameters identified and recorded. (iii) Finally, the review was then internally reviewed by an additional two members of the team (*CMc, MC*), and cross-referenced with other parameter synthesis documents being worked on by the group (*all authors*).

### ***Parameter comparison***

#### ***Parameters of interest***

1. *A-priori* it was decided to harvest parameter estimates for (i) asymptomatic, and (ii) symptomatic cases. As the period of infectiousness can only be estimated indirectly, parameter estimates from the literature was gathered from three different methodological approaches: Virological studies tracking patients overtime undertaking serial testing, where infectious period was inferred from diagnostic testing history and/or by virus isolation.

- 2. Contact tracing studies where infectiousness is inferred by infector-infectee histories and/or clusters of infection.
- 3. Model parameters entered into mathematical models [priors] representing explicitly infectious periods, or model parameters estimated from mathematical models [posterior estimates] estimating explicitly infectious periods

Visual and quantitative comparisons

To compare parameters visually, simulated distributions were estimated from the central tendencies and variation metrics described in the primary literature. To simulate data, 10,000 random variates were drawn from random number functions in Stata (ME, version 15.1; StataCorp. 2017. Stata Statistical Software: Release 15. College Station, TX: StataCorp LLC) [rnormal, rgamma]. Where possible, the distribution reported within the primary literature was used to represent the distribution (e.g. Gaussian, Gamma). Where distributional data could not be inferred, point estimates were presented.

There were adequate comparable data gathered on the duration of T5 (duration from onset of symptoms to death or recovery) from virological studies to employ a meta-analytic model. Many of the studies report different central tendency estimates, including mean and median. Methods of reporting variation across this central tendency included standard deviation, range, inter-quartile range. To facilitate meta-analysis, reported estimates from all studies were converted to the mean and standard deviations based on the formulae given in Wan et al. [21].

To obtain the standard deviations from 95%CI, the method outlined in the Cochrane handbook [22] was used:

$$SD: \sqrt{n(Upper\ limit\ of\ CI - Lower\ limit\ of\ CI)/3.92}$$

Standard Error (SE) was calculated from Standard Deviation (SD) and sample size (n), using:

$$SE = SD/SQRT(n)$$

Comparisons were made using the METAAN package in Stata 15, using the random-effects (DerSimonian-Laird) model.[23] This model assumes heterogeneity between the studies; that is, it assumes that the true effect can be different for each study. The model assumes that the individual-study true effects are distributed with a variance  $\tau^2$  around an overall true effect, but the model makes no assumptions about the form of the distribution of either the within-study or the between-

175 studies effects. Weightings were derived from the standard error [precision] around the estimate.  
176 Comparisons were presented as forest plots. Heterogeneity between studies was tested using  
177 Cochran's Q; the magnitude of the heterogeneity was categorised using  $I^2$  as high (>75%), moderate  
178 (50-75%), or low (<50%).[24]

179 Variation in duration across T5 virological studies was compared using a random effects meta-  
180 regression model, using the METAREG command in Stata 15.1. The hypothesis that heterogeneity  
181 may be related to the inclusion of children or depending on symptom severity within the sample,  
182 was tested in separate univariate models. Severity was dichotomised (0/1) into studies that included  
183 patients described as having 'mild' or 'mild-moderate' symptoms, versus studies that included  
184 patients with 'moderate-severe' or 'severe' symptoms. Similarly, studies were categorised into  
185 having some samples from "children" (as reported in the paper), or wholly adult samples. These  
186 variables were then fitted as a dichotomous dummy predictor [independent]. The parameter  
187 estimates from the regression model was solved using restricted maximum likelihood (REML);  
188 additionally, p-values were estimated using a Monte Carlo model with 1000 permutation test.[25]

189 Raw patient-level data were available from three studies in relation to time from onset to hospital  
190 discharge or death (potentially inferring maximal T5 duration). To estimate the predicted mean and  
191 95%CI duration across these studies, data were analysed using a Gaussian random effects model  
192 (using XTREG command, Stata 15), with study categories fitted as the RE. A linear regression model  
193 with 'study' fitted as a categorical dummy variable was used to estimate the difference between  
194 duration across study datasets. Code and data are provided in Supplementary Material 2 & 3.

### 195 ***Viral dynamics***

196 A narrative comparison of reported viral dynamics from studies that undertook serial viral load  
197 estimates from patients over their period of observation was undertaken. Trends in the literature,  
198 strength and weaknesses were identified, and a conceptual model illustrated.

**Results**

***Parameter comparison***

Overall, 65 parameter estimates were harvested from 48 papers (Tables 1, 2, 3).

*Infectious period for asymptomatic cases (T2)*

The overall distributions and point estimates from studies for T2 are presented in Figure 1 and Table 1.

Two virological studies reported on infectious period based on serial diagnostic testing, for asymptomatic cases, were found to have informative data. One of these studies reported on only one asymptomatic case, with exposure to negative tests being 11 days (Table 1). This duration should be considered an over-estimate, given that a latent period is not taken into consideration. Hu et al. [7] tracked infections of close contacts to infected persons and considered patients asymptomatic at time of diagnosis. Infectious period was defined as time from diagnosis to the first of two clear tests, providing a median duration of 9.5 days (n=24) range: 1 – 21; 3.5-13.0 IQR.

Importantly, Hu et al. [7] found that the infectious period was different between those who subsequently exhibited symptoms (i.e. pre-symptomatic) and those who did not: The median duration for asymptomatic infectious was 6.0 days (IQR: 2.0 - 12.0; N=19). This was reduced to 4.0 days (2.0 - 15.0) for cases that were asymptomatic without abnormal computed tomography (CT) scans (n=7).

Two tracing studies provide informative data (Table 1; [7,8]). Infectious period was inferred indirectly from data provided in Ma et al. [8], whereby infectious period was estimated as the difference between the upper (maximal) latent period estimate minus the serial interval. Ma et al. [8] reports on 49 asymptomatic cases and inferred serial interval from infector-infectee pairs. Serial interval was calculated by assuming “onset” was at first diagnosis. Hu et al. [7] reported on a case-study cluster of infection within a house where the primary case was asymptomatic. Secondary infections occurred 4-9 days after index case exposure, the index patient tested positive until day 29 post exposure.

Modelling studies that have attempted to fit differing parameters depending on the severity of symptoms have used differing nomenclature, for example asymptomatic, “mild” or subclinical cases (Table 1).[14,15,26,27] Two papers by Davies and colleagues [14,15] model this parameter as a gamma distribution with a mean periods of 5-7 days (Fig. 2); importantly, these papers assume infectious period is the same for asymptomatic and symptomatic cases.

### Pre-symptomatic, infectious period (T3)

Pan et al. [3] and Hoehl et al. [28] describe the cases of two individuals tracked and serially tested by real-time reverse transcriptase polymerase chain reaction (RT-PCR) after being exposed to a patient with confirmed infection. In the latter study, the virus was isolated from samples, indicating transmission potential.

Four studies from China, Germany and Singapore provide informative data through tracing infections from cluster of infections, and through infector-infectee pairs (Table 2).[4,9,29,30] These papers included the study by Rothe et al. [9], which clarified that an asymptomatic patient visiting Germany from China may have actually experienced very mild symptoms around the time of transmission occurred (see discussion).

Five modelling papers incorporated pre-symptomatic infectious period reported as prior distributions or estimated as a model output. Two papers describe the prior distribution using a gamma distribution.[14,15] Tindale et al. [31] provide mean point estimates under four different scenarios (two populations, early and late epidemic period). Peak et al. [32] derives estimates of the pre-symptomatic infectious duration from a model of serial interval, and report scenarios where there are pre-symptomatic infectious periods.

The approximated distributions are simulated in Figure 2, which demonstrates the between-study heterogeneity in this parameter. The point estimates primarily cluster around the central tendencies of the distributions, except for Tindale et al. [31], for a model reporting for late occurring cases in Tianjin, China (8.2 days).

### Post-symptom onset, infectious period (T5)

The T5 parameter was informed from three lines of evidence from empirically driven studies:

- time from symptoms onset to the first of two clear RT-PCR tests
- time from symptoms to hospital discharge
- time from symptoms to death

Figure 3 presents the forest plot for the mean time from symptom onset to clearance, based on serial testing meta-analysis (n=15). The mean estimated duration was 13.4 days (95%CI: 10.9-15.8). There was high heterogeneity across studies (Cochrane's Q;  $p < 0.001$ ;  $I^2 > 75\%$ ). A random effects (RE) meta-regression model suggested significant variation depending on whether studies included children as part of the sample (n=15 studies; Proportion of between-study variance explained Adj.  $R^2 = 43.8\%$ ). Overall, the model estimated studies including children had on average 5.8 days

1  
2  
3 261 shorter duration than adult only studies (95%CI: 1.7-10.0; p=0.040; SE(p)=0.003). A second univariate  
4  
5 262 RE meta-regression model suggested that there was non-significant increased mean duration of 4.0  
6  
7 263 days (95%CI: -0.6-8.6; p=0.111; SE(p)=0.005; Adj. R<sup>2</sup> = 22.0%; n=14) for studies that included  
8  
9 264 moderate-severe or severe cases, relative to mild or mild-moderate severity cases.  
10  
11 265 High transmissibility during the first 5 days post symptom onset was described by Cheng et al. [33],  
12  
13 266 based on secondary attack rates for 12 infector-infectee pairs. No contacts (n=1043) with primary  
14  
15 267 cases were infected after five days of the index case onset of symptoms, inferred by the authors to  
16  
17 268 suggest transmission occurring at symptom onset (but conceivably also suggest pre-symptomatic  
18  
19 270 rapidly from onset of infection (distribution was truncated at 30 days); estimated cumulative  
20  
21 271 infectiousness was 66.9% (95%CI: 28.7-94.8) by day 1, and reached 86.9% (95%CI: 64.3-99.5) by day  
22  
23 272 5 post-symptom onset (Figure S2).  
24  
25 273 For tracking studies relating to time to hospital discharge or death, raw case level data were  
26  
27 274 available (studies n=3).[31,34–36] Histograms of the raw data are presented in Figure 4, along with  
28  
29 275 the aggregated distribution. A random effect model suggested a mean duration of 18.1 days (95%ci:  
30  
31 276 15.1 – 21.0). However, there was significant variation across studies, with time to discharge being  
32  
33 277 4.96 days shorter (95%CI: 2.15- 7.76; [35]), or 3.79 days shorter (95%CI: 0.8-6.7; [31]), than time-to-  
34  
35 278 death [34].  
36  
37 279 Two modelling papers use priors (mean: 3.2-3.5 days) to represent clinical infectious period.[14,15]  
38  
39 280 However, the distribution for this parameter is right censored when patients are hospitalised or  
40  
41 281 isolated and therefore not an estimate of the full infectious period *per se*.  
42  
43 282 Infectious period for symptomatic cases (T3+T5)  
44  
45 283 Two tracing studies supplied parameter estimates for the full infectious period for patients who  
46  
47 284 develop symptoms. [8,29] He et al. [29] inferred from a publicly available dataset of 77 infector-  
48  
49 285 infectee pairs that infectiousness began 2.3 days (95% CI, 0.8–3.0 days) prior to symptom onset,  
50  
51 286 peaking at 0.7 days (95% CI, –0.2–2.0 days), and continued up to 7 days from onset. The authors  
52  
53 287 suggest that the transmission risk diminishes 7 days post symptom onset. This suggests that the  
54  
55 288 average infectious period, assuming a symptomatic infectious period of 7 days was approximately  
56  
57 289 9.3 days (7.8-10 days 95%CI, where CI is only reported for the pre-symptomatic period). He et al.  
58  
59 290 [29] estimated that the proportion of all transmission that was pre-symptomatic was 44% (95% CI,  
60  
291 25–69%). Ma et al. [8] analysed data from a number of countries (China, Germany, Japan, Malaysia,  
292 Singapore, Vietnam), collating 1155 cases from public data. They estimate several parameters,

including “maximum latent period” and the serial interval. The authors estimated the infectious period as maximum latent period minus the serial interval. Given their parameter estimates and methodological approach, infectious period would have been 5 days (range 0-24; IQR: 2-9; calculated from data presented within the paper).

Seven modelling papers reported duration of infectious period ( $T_3+T_5$ ; Table 4), with the reported central tendency for the distribution varying from 3-20 days. The form of the distribution offered to models for this parameter varied considerably, including point estimates (deterministic models), flat (uniform), Gaussian, Weibull and gamma distributions. Li et al. [27] estimated the shortest median duration of 3.45 days, with a flat (uninformative) prior distribution corralled between 3-5 days. In contrast, Zhu et al. [37] used a mean prior of 10 days, with the model estimated mean duration being 12.5 days (variance 10; Weibull distribution). Piccolomini and Zama [38] used a fixed estimate of 20 days infectious period, to model the Italian epidemic. Two papers from the same group [14,15] suggested that infectious period for asymptomatic cases approximated for symptomatic cases where there was no right censoring (that is, transmission being halted through isolation or hospitalisation; gamma distributions of mean 5 or 7 days). Tuite et al. [26,39] also assumed the same duration for “mild” and “severe” symptomatic cases (6-6.5 days).

***Viral load dynamics***

Viral load was reported from 21 papers using real-time reverse transcriptase polymerase chain reaction (rRT-PCR) testing, generally post-symptomatic monitoring.[3,29,40–59] Qualitatively, the viral dynamics described early increase in viral load, peaking around onset or within 2-4 days of symptom onset (Figure 5 for a theoretical model), before decreasing gradually over the next one to three weeks post symptom onset. Maximum duration of detection ranged from approximately 20-49 days, with the longest duration associated with faecal samples (see below for discussion). The duration where ribonucleic acid (RNA) was recoverable by RT-PCR may have been truncated due to insufficient follow-up in some cases. Studies that have investigated blood samples have provided some evidence for an association with severity of infection [16,60], though it is not clear whether this is a consistent feature of SARS-CoV-2 infection [40].

It should be noted the lack of data on pre-symptomatic or asymptomatic cases with regards viral load. An exception was Kam et al. [61] who describe a pre-symptomatic case in an infant. In another study, Zou et al. [53] undertook serial RT-PCR testing from nasal and throat swab samples from 14 imported cases, and 4 secondary cases, in Guangdong, China. The dynamics of the infection in terms of cycle threshold (Ct) values and RNA copy number were described; Ct values of 30.76, 27.67, 24.56, and 21.48 corresponding to  $1.5 \times 10^4$ ,  $1.5 \times 10^5$ ,  $1.5 \times 10^6$ , and  $1.5 \times 10^7$  copies per milliliter. Hence, lower Ct values infer higher viral loads. The authors report on a patient without symptoms, but with positive nasal swabs (Ct values, 22 to 28) and throat swabs (Ct values, 30 to 32) testing positive on days 7, 10, and 11 after contact. Importantly, the authors suggest “the viral load that was detected in the asymptomatic patient was similar to that in the symptomatic patients.”

Furthermore, Kimbell et al. [62] report that Ct values between asymptomatic (21.9 to 31.0), pre-symptomatic (15.3 to 37.9), and symptomatic cases (18.6 to 29.2) within a nursing home environment did not differ significantly. To et al. [59] present data on temporal profile of viral load from saliva samples, and found that median initial and peak viral loads in severe cases were non-significantly higher ( $p>0.5$ ) by approximately 1 log10 higher than those in mild cases. Liu et al. [58] present data showing viral load being 60 times greater for severe cases relative to mild cases.

This lack of pre-symptomatic data may result in left truncation of the risk distribution associated with viral load and shedding. Therefore, the typical timing of peak viral shedding (whether prior to, at, or after onset), and it’s impact on transmission, is still uncertain. He et al. [29] reported highest viral load at symptom onset from patients sampled in a hospital in China. Furthermore, the author’s estimate using a separate infector-infectee dataset (n=77) that 44% (95% CI: 25–69%) of infectee cases were infected during the pre-symptomatic stage of the infector. Separately, a modelling paper

by Ferretti et al. [63] also appears to support this, estimating that 47% (0.9/2) of total transmission contributing  $R_0$ , an overall measure of transmission during an infection, was pre-symptomatic (also see [33]).

Wölfel et al. [50] provides important data on a cohort of nine 'mild' cases which were serially tested using sputum, swabs (throat and nasopharyngeal), urine and faecal samples over time. Importantly, the virus was isolated, and inferences on viral replication could be made. Viral Isolation, and insights into viral replication, improve inference around viral dynamics and transmission risk. The study suggested high viral loads shortly after symptom onset, which declined thereafter over time. Positive cultures were found from day 3-8 post-symptom onset (Figure S3), and the minimum 5% isolation success was achieved up to 9.8 (95% CI: 8.5-21.8) days post onset from throat and lung samples but not faeces, blood or urine.

**Discussion**

Inferring infectiousness was challenging given the heterogeneity of evidence available. Virological diagnostic studies provide robust time series of infection, however, is limited by inferring the relationship between PCR diagnostics and infectiousness. These data can also be affected by sampling procedure and sample sites (e.g. upper respiratory, lower respiratory, faeces, urine, blood). We have excluded RT-PCR durations based on faecal sampling due to the current uncertainty whether these data pertain to transmission potential ([50]; see below). Virological studies where culturing has taken place, and where viral replication can be inferred would also be considered superior data to infer infectious period, relative to estimates of viral load alone.[50] Where this has taken place, the data would suggest average infectious periods of up to 9.8 days post-symptoms. Recent modelling work suggest that the duration of viral detectability could overestimate the infectious period somewhere between 2-6 days.[64]

Viral load studies suggest peak viral load occurs close to symptom onset (potentially, -1 to 7 days of onset), however there is uncertainty whether this typically occurs prior to, on, or after onset (Figure 5 for conceptual model). High viral loads, measured as Ct values, have been recorded for one week to 20 days post symptom onset, with a general decreasing trend with time. For example, To et al. [59] estimates a declining slope per day for log10 RNA copies per ml of -0.15 (95% CI -0.19 to -0.11;  $R^2=0.71$ ). There are some studies reporting associations between viral load and symptom severity, with higher metrics of viral load in severe cases.[3,58,59] However, Zou et al. [53], and more recent data from Italy,[64,65] suggest similar viral loads in symptomatic and asymptomatic cases.

We tested the hypothesis that severity of symptoms had an effect on symptomatic infectious duration using a meta-regression approach. There was a trend towards studies that included severe cases tended to have longer duration (estimated to be 4.0 days longer), but the effect was not significant. Some studies have reported an association between duration of infectiousness and severity (e.g. [58]). But uncertainty of whether this is robust remains. Caution is required when comparing severity of symptoms, as objective or standardised metrics are not always reported.

Virological studies that included children (either mixed adult children, or children only cohorts) appeared to have shorter T5 durations (estimate: 5.8 days shorter). Liao et al. [66] present data which suggests that children and ‘young adults’ (<35 years old) infected cases exhibited long incubation time (exposure to symptom on-set; mean 7.2 days), and short serial interval (mean 6.5 days; median 1.9 days; time from onset in primary to onset in secondary case).

Contact tracing studies provided robust evidence of transmission events, and therefore infectiousness, but can be limited by the inferred timing of events, and symptoms experienced, due to the self-reported nature of data collection (recall bias). The subjective nature of self-reporting indeed can have an impact on case definitions of 'asymptomatic', which has led to some doubt on asymptomatic transmission in one case.[9] Rothe et al. [9] describe a case of apparent asymptomatic transmission from a Chinese visitor to business associates in Germany, which was cast into doubt when health officials reported that the patient had indeed experienced some, albeit minor, symptoms.[67] Rothe et al. [9] subsequently updated the clarification of the patients self-reported symptoms during the presumed asymptomatic infectious period, which included "feeling warm" and "feeling cold". However, the patient only "recognized getting sick" after she returned to China on day four after the presumed exposure event.

Modelling parameters provide information on how COVID-19 data are being used and interpreted in the research community, given the limited data available. Posterior estimates also provide information on the parameter space at which infectious period central tendency reside, given other parameters and assumptions in the model. Models used highly varied approaches to modelling infectious period, which in turn resulted in highly variable parameter estimates used to inform the studies. An important factor to consider when comparing parameter estimates between empirical and modelling studies is the interpretation of the parameter by different disciplines, and even between researchers from the same discipline. The infectious period can be considered significantly context specific and dynamic, and the ability to transmit infection can be modulated by interventions (e.g. through isolation or hospitalisation). Modelling papers, depending on the model structure, can report truncated infectious period accounting for such interventions. Such estimates are not comparable with our definition of the parameters reviewed, and we have attempted to avoid such disparities where we found them.

#### *Overall duration findings*

There are few data for the precise definition of the asymptomatic infectious period (T2) parameter. Some reported asymptomatic cases can actually be pre-symptomatic, when cases are subject to follow-up (e.g.[66]; see discussion above). However, Hu et al. [7] do provide the data for asymptomatic cases [that remain asymptomatic] across their presumed infectious period. Therefore, in the first instance a parameter mimicking their data is probably the best available data over the period of the present study. Note, there is a large variation in this data parameter, and a gamma distribution of a shape alpha 3, beta 2, mean 6, may be appropriate for the initial model runs. Despite these being the primary informative data, caution is required, given the uncertainty around

1  
2  
3 418 the relationship between RT-PCR results and infectiousness. Overall, an informed central tendency  
4  
5 419 of ~6 days, with very low probability draws for durations >20 days for the T2 parameter may be  
6  
7 420 considered given the current state of knowledge.  
8  
9 421 The pre-symptomatic period is sometimes referred to as ‘preclinical infectious’ period (parameter  
10  
11 422 T3). This has been estimated from several papers, and the central tendency of these estimates vary  
12  
13 423 from <1 - 4 days, cautiously approximating to 2 days, on average. Current models have used central  
14  
15 424 tendency estimates of 0.5 to 2.4 days.[14,15,26,39] The relative consistency around the duration of  
16  
17 425 this period allows for some confidence of its distribution. Current understanding of viral dynamics of  
18  
19 426 infection suggest that viral load and shedding increases during post-latent phase, peaking around  
20  
21 427 onset [for symptomatic cases], before declining.[29,50,53] This aspect of the natural history of  
22  
23 428 infection may be important when attempting to model transmission dynamics.  
24  
25 429 Length of infectious period in symptomatic cases that do not isolate (T5 parameter) has also been  
26  
27 430 rarely directly measured in the literature, as serial monitoring of patients in terms of symptoms or  
28  
29 431 viral load (rt-PCR) generally occurs after diagnosis and/or after admission to hospital [from a  
30  
31 432 modelling perspective, this means cases are censored as they are assumed to no longer contribute  
32  
33 433 to transmission]. If natural progression of infection after diagnosis or hospital admission mimics the  
34  
35 434 course of infection for those who do not isolate, the review of the literature describing time to two  
36  
37 435 clear tests is informative. Symptom onset to serial testing clearance [assessed the time to first of two  
38  
39 436 RT-PCR clear tests] averaged 13.4 days from our meta-analysis. In the maximal case, where patients  
40  
41 437 succumb or fully recover from infection, time from symptoms to death or discharge may be  
42  
43 438 informative. Studies that collated such information suggest mean durations of 18.07 days, but with  
44  
45 439 time to discharge being 4.96 days shorter on average than time to death. These values may  
46  
47 440 represent an over estimation of the infectious period; one study suggested that there was on  
48  
49 441 average 2.5 days between end of infectiousness and ‘removal’ (recovery or death).[37]  
50  
51 442 Cheng et al. [33] provided evidence of transmissibility, based on attack rate from primary to  
52  
53 443 secondary cases, at around symptom onset. The authors estimate cumulative infectiousness from  
54  
55 444 onset, which suggests that 67% of total infectiousness potential occurs by the first day post-onset.  
56  
57 445 Most of the total infectiousness occurs within 5 days (86.9%) post onset, with the remaining  
58  
59 446 infectiousness potential (13.1%) being distributed up to day 30 (this truncation is an assumption by  
60  
61 447 the authors). It is possible that pre-symptomatic transmission occurred during this study, but the  
62  
63 448 authors do not estimate what proportion of transmissions occurred during a pre-symptomatic  
64  
65 449 infectious period, or its potential duration.

A model by He et al. [29] is informative for overall symptomatic duration (T3+T5), using 77 infector-infectee pairs where COVID-19 transmission occurred in China. The study reported that infectiousness was apparent on average 2.5 days prior to symptoms, reached a peak in risk at 0.6 days before symptoms, and decline up until 7 days after onset (9.5 days total infectious period). The proportion of transmission before symptom onset (area under the curve) was estimated as 44% (95% CI, 25–69%), based on inferences on incubation period. The authors suggest their data supported the view that transmission risk decline substantially after 7 days post-symptoms onset.

Model estimates used for infectious period parameter appears to be shorter than virological studies tracking RNA viral load over time. For example, Liu et al.[27] fitted a flat prior distribution for mean duration ( $D$ ) fixed to vary between:  $2 \leq D \leq 5$  days, and Lavezzo et al. [64] fixed infectious period to 2 days in their epidemic model; whereas viral repeat testing studies provide evidence to suggest high viral loads can be detected to up 20 days (e.g. pharyngeal swabs), and potentially longer from faecal samples (up to 3-4 weeks post symptoms onset)). Oral-faecal transmission risk is currently unknown, but some doubt has been raised about studies that have reported positive RTPCR test results (see [68]; but there may be some evidence of the risk amongst children; [69]). Wölfel et al. [50] has produced an important study that provides some data on viral replication, and the site and duration over which this may be taking place. Their data suggests that viral replication, with high viral loads, occur in the upper respiratory tract, over the first week of symptoms peaking in day 4. Virus could not be isolated from faecal samples, despite high RNA concentration. Furthermore, virus was not isolated from blood or urine in that study.[50]

It should be noted that some of the virological and tracing studies reviewed had small sample sizes (see Study Limitations) and potentially biased towards more severe cases or clusters of infection. It is unknown as to whether these cases are representative of infectious duration generally across populations. However, if symptom severity is linked to infectious duration, one could speculate that this bias could help to explain the some of the difference between model and empirical duration estimates.

### Study limitations

Overall, the studies included were of good quality, though due to the rapid need for information from the global research community many papers are pre-prints that have yet to be reviewed (at time of writing). Many papers were limited in terms of sample sizes, with several papers being case studies of one patient or single cluster outbreaks. There was a diversity of methods employed to infer dynamics of infectiousness across studies, and therefore the evidential base was variable. Some issues around nomenclature were noted, including definitions of asymptomatic, infectious period,

1  
2  
3 483 latent, and incubation period. It is possible the same data may have been used across different  
4  
5 484 studies, especially where publicly available data were used.  
6  
7 485 There was significant heterogeneity across study findings, and this was related to diversity of clinical  
8  
9 486 findings and methods employed. The meta-analysis employed for one parameter (T5) using  
10  
11 487 virological studies, where cross study comparisons could be made, suggested that the heterogeneity  
12  
13 488 was high. Fu et al.[70] cautions against combining studies to give an overall estimate without  
14  
15 489 exploring subgroup or meta-regression analysis, which we have done here. The meta-regression was  
16  
17 490 based on a small number of studies (n=12-13). Cochrane’s handbook suggests 10 studies for each  
18  
19 491 level of a meta-regression, however in practice much lower numbers have been used to test  
20  
21 492 hypotheses [22], as is the case here. Fu et al. [70] recommend a minimum of 4 studies per category,  
22  
23 493 and therefore we dichotomised our predictor variables to ensure we met this minimum. Aggregating  
24  
25 494 our categories resulted in crude findings.  
26  
27 495 Another limitation is that a systematic review was not undertaken to inform this research, hence  
28  
29 496 there is a possibility that some relevant studies were overlooked. However, two independent  
30  
31 497 research groups conducted comprehensive search strategies as part of a broader epidemiological  
32  
33 498 parameters project for COVID-19 [12,13,71,72,73] to inform this research, hence limiting the  
34  
35 499 potential for missing key studies.

36 500 **Conclusion**

37 501 There are few data to inform asymptomatic infectious period (T2 parameter). One study provide  
38  
39 502 data that suggest a median period of 4-9.5 days, however, given the viral dynamics, this distribution  
40  
41 503 could have an extended tail with low probability long infectious periods of up to 20 days. The pre-  
42  
43 504 symptomatic infectious phase (T3) is quite narrowly defined to a mean of approximately 2 days  
44  
45 505 (range: <1-4) within the literature. However, there is great uncertainty around the infectious period  
46  
47 506 from onset to recovery or death (T5 parameter). The symptom onset until clearance (based on two  
48  
49 507 negative RT-PCR tests) parameter estimate of 13.4 days (95%CI: 10.9-15.8) is informative for T5  
50  
51 508 parameter, only if one assumes that RT-PCR positive results equate to having infectious potential.  
52  
53 509 Many current models corral the infectious period to shorter time periods than what virological  
54  
55 510 studies have suggested, with one recent study suggesting that duration of viral detectability over-  
56  
57 511 estimates the infectious period on average by 2-6 days. While viral RNA can be detected for long  
58  
59 512 periods of time, especially from faecal samples, the ability to isolate the virus from Infected cases  
60  
513 quickly declines after one-week post-symptoms. Some modelling papers have assumed that  
514  
515 514 infectious period is invariant to whether cases are asymptomatic or symptomatic, however, the data  
516  
517 515 available are not yet rich enough to inform whether this is a good assumption. Similarly, it is not yet

established whether viral loads are similar between asymptomatic and mild, moderate, or severe symptomatic cases, with conflicting reports in the literature.

**Tables and figures**

**Figure 1:** Simulation of the parameter distribution inferred for duration infectious period for asymptomatic cases (T2) inferred infectious period for Davies et al. (2020a), grey/blue curve, Davies et al. (2020b) pink curve [model priors]. Green curve: Ma et al. (2020). Histogram is the distribution of asymptomatic cases to two clear tests reported by Hu et al. (2020). Reference lines are point estimates reported from Zhou et al. (2020), Li et al. (2020), and Tuite et al. (2020a & b).[7,8,14,15,26,27,39,71]

**Figure 2:** Simulation of the parameter distribution used for T3 (the duration of the pre-symptomatic infectious period for those infected individuals who subsequently develop symptoms). Curves represent simulated approximations of distributions, given information provided from primary literature. Vertical lines represent point estimates where distributions could not be inferred (see table 2). 1. Peak et al. [posterior]; 2. Davies et al. 2020b [prior]; 3. Rothe et al. 2020; 4. He et al. 2020; 5. Davies et al. 2020a [prior]; 6. Wei et al. 2020. [9,14,15,29,30,32]

**Figure 3:** Forest plot of the mean duration from onset of symptoms to death or recovery (T5) based on virological studies

**Figure 4:** Frequency distribution of **T5**, time from onset of symptoms to recovery (here hospital discharge or death), using patient level raw data from Kraemer et al. ([35,36]; pink bars), Linton et al. ([34]; purple bars) and Tindale et al. ([31]; green bars). Blue solid line is the kernel density of the aggregated dataset Dashed lines represent the mean and 95%CI from a random effects regression model.

**Figure 5:** Composite inferred model for cycle threshold (CT) value changes from serial RT-PCR testing for SARS-COV2; currently uncertain whether peak viral load typically occurs prior to, on, or post-symptom onset (primary literature informing this model includes [29,50,53,59]).

**Table 1:** Reported infectious period (IP) for asymptomatic cases (T5 parameter) from virological studies where serial diagnostic tests were undertaken to infer IP; tracking studies where IP is inferred from contact tracing; modelling studies where IP is reported as a prior (assumed parameter value) or an posterior estimate.

No.	Study	Countries	Parameter (days)	n	Central tendency reported	Variation (days; inclus.)	Comment
<b>Virological studies</b>							
[74]	Zhou et al. (2020)	China	11 days	1	Max		This study <b>serially swabbed and tested</b> symptomatic (17) and asymptomatic (1) cases via RTPCR. The single asymptomatic case tested positive up to 11 days post contact with an infected patient (presumed point of exposure).
[7]	Hu et al. (2020)	China	9.5 days	24	Median	1-21 range	<b>Serial testing.</b> Period between “onset” (where onset relates to first positive test) and clearance, adjudged via two negative RTPCR tests, deemed by the authors to be the ‘communicable period’. IQR: 3.5-13
<b>Tracking studies</b>							
[8]	Ma et al. (2020)	China, Germany, Japan, Singapore, South Korea, Malaysia, Vietnam	7.25 days*	49	Mean	5.91-8.69 (95%CI)	*Ma et al. (2020) does not report infectious period for asymptomatic cases explicitly within their paper. The authors estimated the infectious period as the upper estimated latent period minus the serial interval, using a dataset of 1155 cases from several countries (latent period was estimated with 11 infector-infectee pairs; serial interval was estimated from 689 infector-infectee pairs). Ma et al. (2020) reported a mean upper limit of latent period of 2.52 days; the mean serial interval for asymptomatic cases (using date of diagnosis for onset) was estimated to be 9.77 (94%CI: 8.43, 11.21).

[7]	Hu et al. (2020)	China		3		4-9 range	Cluster of infection within a family, where the primary case was asymptomatic. The transmissions to secondary cases occurred over a period 4-9 days post the presumed point of exposure for the primary case.
<b>Modelling studies</b>							
[27]	Li et al. (2020)	China	3.5* [posterior from a model estimating duration for undocumented cases]		Median	3.19-3.78 95%CI	Li et al. (2020) do not explicitly attempt to model asymptomatic cases, or their infectious duration. Instead the population infected is divided into 'documented' and 'undocumented'. Documented were all cases where patients had symptoms severe enough to be confirmed infected; all other cases were considered undocumented. Therefore, this estimate represents asymptomatic and 'mild' cases. The 95%CI around the median infectious period estimate was 3.19-3.78
[26,39]	Tuite et al. (2020a &b)	Canada	6-6.5 [Prior]		[Fixed parameter within a deterministic model]		Mathematical model [deterministic], with a fixed parameter estimate of 6 or 6.5 days. Important to note that duration for 'mild' was equal to severe cases.
[14]	Davies et al. (2020) (a)	UK	7 days [Prior]		Mean		Model with asymptomatic infection compartment. Modelled with a gamma distribution, beta 1.4; alpha 5. Despite, the subclinical aspect of this parameter, it could be considered analogous to total infectious period without intervention.
[15]	Davies et al. (2020) (b)	UK	5 days [Prior]		Mean		Model with asymptomatic infection compartment. Modelled with a gamma distribution, k=4. Authors: "Assumed to be the same duration as total infectious period for clinical cases, including preclinical transmission"

815

**Table 2:** Reported infectious period (IP) for pre-symptomatic cases (T3 parameter) from virological studies where serial diagnostic tests were undertaken to infer IP; tracking studies where IP is inferred from contact tracing; modelling studies where IP is reported as a prior (assumed parameter value) or an posterior estimate.

	Study	Location	Parameter (days)	Central tendency reported	Variation (days; inclus.)	Comment
<b><i>Virological studies</i></b>						
[3]	Pan et al. (2020)	Beijing, China	1	Median		Case study of two individuals tracked due to exposure to an infected patient was <b>serially tested</b> prior to onset of symptoms.
[28]	Hoehl et al. (2020)	Flight from Wuhan to Germany	1	Median		Case study of <b>serially tested</b> at risk cohort flying from Wuhan to Germany. Two patients were asymptomatic test positive; additionally virus isolation was achieved, indicating potential infectiousness.
<b><i>Tracking studies</i></b>						
[4]	Huang et al. (2020)	Nanjing, China	4	Median	3-5 range	Follow-up <b>tracing</b> case study cluster of infection within a family demonstrating pre-symptomatic infection (n=10)
[9]	Rothe et al. (2020)	Germany	2	Median	1-3 range	<b>Tracing</b> case study of a cluster of infections whereby pre-symptomatic transmission occurred (n=3).
[29]	He et al. (2020)	Vietnam, Malaysia, Japan, China, Taiwan, USA, Singapore	2.3	Mean	95% CI, 0.8–3.0	<b>Tracing</b> paper infector-infectee pairs. Estimated from serial interval and incubation periods. N=77
[30]	Wei et al. (2020)	Singapore	2.5	Median	2-3 (IQR)	<b>Tracing</b> study investigating pre-symptomatic infections from primary cases to secondary cases in 7 clusters. N=8 primary cases. T3 estimated as the min. days between transmission period (TP) and primary case

						symptom onset, when TP straddled >1 day. Range: 2-6 days.
<b>Modelling studies</b>						
[32]	Peak et al. (2020)	Massachusetts	0.8 [estimate]	Mean	-0.29-1.98 95% CI*	<b>Modelling paper</b> estimated under two scenarios – a serial interval of 4.8 days or 7.5 days. Under scenario one, the model estimated a period of pre-symptomatic transmission (median: 0.71). * the lower range was fixed at zero as the model allowed for no pre-symptomatic infectious case.
[37]	Zhu et al. (2020)	Wuhan, China	1.0 [estimate]	Mean		<b>Modelling paper.</b> Model estimated point value – This is a model derived value
[14]	Davies et al. (2020) (a)	UK	2.4 [prior]	Mean		<b>Modelling paper.</b> Gamma distribution; k=5.
[15]	Davies et al. (2020) (b)	UK	1.5 [prior]	Mean		<b>Modelling paper.</b> Gamma distribution: k=4
[26,39]	Tuite et al. (2020a & b)	Canada	0.5, 1 [prior]	Fixed		<b>Modelling paper.</b> Fixed parameter within a deterministic model.
[75]	Ferguson et al. (2020)	UK	0.5 [prior]	Fixed		<b>Modelling paper.</b> Fixed parameter within this model, whereby infectiousness was assumed to begin 12 hours symptom onset.
[31]	Tindale et al. (2020)	Tianjin, China, and Singapore	2.9-2.6 [estimate]	Mean	1.2-8.2 mean range, depending on early or late cases, or whether in Tianjin, Singapore	Statistical <b>modelling</b> study estimating period pre-symptomatic transmission inferred from estimates of serial interval and incubation periods for populations in Tianjin and Singapore (n=228).

820

821

**Table 3:** Reported infectious period (IP) for post-symptomatic cases (T5 parameter) from virological studies where serial diagnostic tests were undertaken to infer IP [onset to  $\geq 2$  tests]; tracking studies where IP is inferred from patient histories from onset to recovery or death; modelling studies where IP is reported as a prior (assumed parameter value) or an posterior estimate.

No.	Study	Location	Parameter (days)	Central tendency reported	Variation (days; inclus.)	Comment
<b>Virological studies</b>						
[76]	Cai et al. 2020 (a)	China	12	Median	6-22 range	<b>Serial testing</b> study of n=10 mild cases RT-PCR confirmed in children. IQR: 8-15 days
[77]	Cai et al. 2020 (b)	China	14	Median	9-19 (IQR)	<b>Serial testing</b> study with n=298 confirmed (RT-PCR) cases treated within hospital setting
[78]	Chen et al.(2020)	China	12	Max.		Single case study for a patient admitted to hospital where RT-PCR <b>serial testing</b> was undertaken. Patient had an additional positive test at day 17, but subsequently tested negative
[79]	Cheng et al. (2020)	China	21	Max.		Case study of single patient <b>serially tested</b> by RT-PCR
[7]	Hu et al. (2020)	China	12	Median	12-14 (IQR)	<b>Serial testing</b> study of patients who were first tested (qRT-PCR) when asymptomatic; this subset subsequently developed symptoms (n=5).
[42]	Kim et al. (2020)	Korea	15.5	Median	14-17 (range)	<b>Serial testing</b> of two confirmed cases via RT-PCR. Viral load highest during early phase of infection (day 3-5).
[43]	Kujawski et al. (2020)	USA	26	Max.		<b>Serial testing</b> of two confirmed cases via RT-PCR. Mild to moderate symptoms.
[80]	Lee et al. (2020)	Taiwan	20	Max.		<b>Serial testing</b> (RT-PCR) of a single patient hospitalised presenting with pneumonia
[44]	Lim et al. (2020)	South Korea	16	Max.		<b>Serial testing</b> (RT-PCR) of a single patient hospitalised presenting with pneumonia. Two clear tests day 11, virus

						detectable again up to day 16.
[81]	Ling et al. (2020)	China	9.5	Median	2-22 (range)	<b>Serial testing</b> of two confirmed cases via RT-PCR. n=66. IQR: 6-11 days, oropharyngeal sampling. Mix of adult and children.
[82]	Liu et al. (2020)	China	11	Median	7-18 range	<b>Serial testing</b> of two confirmed cases via RT-PCR. n=10. 10-13 (IQR); adults, mild, moderate, and severe cases.
[45]	Marchand-Senéca et al. (2020)	Canada	23	Max		<b>Serial testing</b> (RT-PCR) of a single patient hospitalised presenting with pneumonia.
[3]	Pan et al. (2020)	China	10	Median	8-12 range	<b>Serial testing</b> (RT-PCR) of two patients hospitalised. Viral loads peaked days 5-6 post-onset.
[83]	Qu et al. (2020)	China	22	Max		<b>Serial testing</b> (RT-PCR) of a single patient hospitalised
[46]	Tan et al. (2020)	Vietnam	16	Max		<b>Serial testing</b> (RT-PCR) of a single patient hospitalised; throat sample.
[47]	Thevarajan et al. (2020)	Australia	7	Max		<b>Serial testing</b> (RT-PCR) of a single patient hospitalised; throat sample. Highest viral load on first test at day 4 in nasopharyngeal; day 6 for sputum.
[69]	Xing et al. (2020)	China	14	Median		<b>Serial testing</b> (RT-PCR) of a three (children) patients hospitalised. Mild-moderate infecting. Positive viral samples from faeces up to 4 weeks post-symptoms.
[52]	Young et al. (2020)	Singapore	12.5	Median		<b>Serial testing</b> (RT-PCR) of 18 patients hospitalised. Adults. Viral load peaked over testing series at day 4 since onset.
[84]	Yuan et al. (2020)	China	6	Median	4-10 (IQR)	<b>Serial testing</b> (RT-PCR) of 25 patients hospitalised. Children and adults. "Non-severe" cases.
[74]	Zhou et al. (2020)	China	20	Median	16-23 IQR	<b>Serial testing</b> (RT-PCR) of 191 patients hospitalised in two hospitals. Adults. 54 died. Survivors (n=137); Median (IQR) 20.0 days (17.0–24.0); Non-survivors

						(n=54); Median (IQR) 18.5 days (15.0–22.0); Shedding continued until death. Inferred shedding period; 8–37 days.
[85]	Chen J. et al. (2020)	China	11	Median	10–12 (95%CI)	<b>Serial testing</b> (RT-PCR) of 242 patients hospitalised. Adults. 90% mild/asymptomatic; 10% severe/critical.
[60]	Fang et al. (2020)	China	15.7	Mean	6.7 (sd)	<b>Serial testing</b> (RT-PCR) of 24 non-ICU patients hospitalised. Adults. Nasal samples.
[60]	Fang et al. (2020)	China	22.3	Mean	3.6 (sd)	<b>Serial testing</b> (RT-PCR) of 8 ICU patients hospitalised. Adults. Nasal samples.
[57]	Hill et al. (2020)	Scotland	9	Max.		<b>Serial testing</b> (RT-PCR) of a single patient (adult) hospitalised; nasal sample [throat sample: 6 days]. Mild.
[86]	Le et al. (2020)	Vietnam	12	Max.		<b>Serial testing</b> (RT-PCR) of a single patient (infant) hospitalised. Mild.
[58]	Liu et al. (2020)	China	10	Max.		<b>Serial testing</b> (RT-PCR) of patients hospitalised. Adults. Mixed Mild/severe cases. N=76. 90% “early viral clearance” within 10days
[87]	Qiu et al. (2020)	China	10	Mean	7–22 range	<b>Serial testing</b> (RT-PCR) of patients hospitalised. Children. N=36. Mild and moderate cases.
[59]	To et al. (2020)	Hong Kong	25	Max.		<b>Serial testing</b> (RT-PCR) of patients hospitalised. N=7. Seven patients reported viral detection >20 days; viral load peaked during first week post-onset of symptoms.
[88]	Wu et al.	China	16.1	Mean	6.7 (sd)	<b>Serial testing</b> (RT-PCR) of patients hospitalised. Adults. N=74. Severe and non-severe cases.
<b>Tracking studies</b>						
[31]	Tindale et al. (2020)	Singapore	18	Median	9–33 range	Time from onset to discharge; range 9–33; n=53

[35,36]	Kraemer et al. (2020a); [later published as: Xu et al. 2020]	Various	19	Median	3-37 range	Time from onset to discharge; Range: 3-37; n=70
[34]	Linton et al. (2020)	Wuhan, China	13	Median	6-41 range	Time from onset to death; range 6-41
[35,36]	Kraemer et al. (2020b)	Japan and China	19.25	Mean	12-24 range	Time from onset to death; n=4
[49,50]	Wölfel et al. (2020)	Germany	3-8 days	absolute	3-8 range	Tracked infection in mild cases in Germany, undertaking viral isolation studies to assess active replication across a number of samples sites (upper respiratory tract, blood, urine, faeces) over the duration of infection. 5% isolation success was achieved up to 9.78 (95% CI: 8.45-21.78) days post onset; n=9

826

827

review only

**Table 4:** Reported infectious period (IP) for symptomatic cases (T3+T5 parameter) from virological studies where serial diagnostic tests were undertaken to infer IP [exposure to  $\geq 2$  neg. tests]; tracking studies where IP is inferred from patient histories from onset to recovery or death; modelling studies where IP is reported as a prior (assumed parameter value) or an posterior estimate.

No.	Study	Location	Parameter (days)	Central tendency reported	Variation (days; inclus.)	Comment
<b>Tracking studies</b>						
[29]	He et al. (2020)	Vietnam, Malaysia, Japan, China, Taiwan, USA, Singapore	9.3 days	Mean	7.8-10 (95%CI*)	The paper reported on 77 infector-infectee pairs which were sequential/serially tested, using publicly available data. Viral dynamics (Guangzhou, China; N=94) interpreted by the authors suggested an infectious period starting 2.3 (95% CI, 0.8–3.0 days) days prior to symptoms, peaking 0.7 days (95% CI, –0.2–2.0 days), continuing up to 7 days from onset. * CI from pre-symptom infectious period only.
[8]	Ma et al. (2020)	Various	~5 days	Median	Range 0-24	The authors estimated the infectious period as latent minus the serial interval, using a dataset of 1155 cases. Range 0-24; IQR: 2-9; calculated from data presented within the paper.
<b>Modelling studies</b>						
[27]	Li et al. (2020)	China	3.45 days [posterior estimated from model for documented cases]	median	95%CI for the mean: 3.19, 3.72	Mathematical model. Priors for <u>mean</u> documented infectious period was a flat [uniform] distribution 2-5. 'Documented' cases were defined as those severe enough to be confirmed. This corraling of the infectious period relative to other

						studies should take into account that the distribution is used for the central tendency, not the whole distribution.
[26,39]	Tuite et al. (a, b) (2020)	Canada	6-6.5 days [prior; fixed parameter within a deterministic model]	Fixed parameter		Mathematical model [deterministic], with a fixed parameter estimate of 6.5 days (a) and 6 days (b), respectively. Important to note that duration for 'mild' was equal to severe cases.
[89]	Lourenco et al. (2020)	UK	~3-5 days [posterior; approximate depending on scenario tested]	mean	95%ci of 3-6 days	Mathematical model. The prior used was given a Gaussian distribution (normal curve); mean 4.5; SD 1; approximate 95%ci of 3-6 days. The reported posterior of this parameter was presented graphically and depended on R0 and proportion at risk. Depending on the scenarios tested, mean duration of infectiousness appeared to vary from 3-5 days.
[37]	Zhu et al. (2020)	Wuhan, China	12.5 days [posterior estimated from model]	Mean	11.4 variance	Mathematical model. The parameter was estimated using a Weibull distribution. The prior for this parameter was 10 days. The posterior variance around the mean was 11.4, and therefore the distribution had a long tail. This study was a modelling [SEIR extended model].
[15]	Davies et al. (b) (2020)	UK	7 days [Prior]	Mean		Model with asymptomatic infection compartment. Modelled with a

						gamma distribution, beta 1.4; alpha 5. Despite, the subclinical aspect of this parameter, it could be considered analogous to total infectious period without intervention.
[14]	Davies et al. (b) (2020)	UK	5 days [Prior]	Mean		Model with asymptomatic infection compartment. Modelled with a gamma distribution, k=4. Authors: "Assumed to be the same duration as total infectious period for clinical cases, including preclinical transmission"
[38]	Piccolomini and Zama (2020)	Italy	20 days [Prior]	Fixed		Parameter estimate assumed for the infectious period within an SEIRD model, fitted to data from the epidemic in Italy.

## Preferred Reporting Items for Systematic reviews and Meta-Analyses extension for Scoping Reviews (PRISMA-ScR) Checklist

SECTION	ITEM	PRISMA-ScR CHECKLIST ITEM	REPORTED ON PAGE #
<b>TITLE</b>			
Title	1	Identify the report as a scoping review.	1
<b>ABSTRACT</b>			
Structured summary	2	Provide a structured summary that includes (as applicable): background, objectives, eligibility criteria, sources of evidence, charting methods, results, and conclusions that relate to the review questions and objectives.	2
<b>INTRODUCTION</b>			
Rationale	3	Describe the rationale for the review in the context of what is already known. Explain why the review questions/objectives lend themselves to a scoping review approach.	3
Objectives	4	Provide an explicit statement of the questions and objectives being addressed with reference to their key elements (e.g., population or participants, concepts, and context) or other relevant key elements used to conceptualize the review questions and/or objectives.	3
<b>METHODS</b>			
Protocol and registration	5	Indicate whether a review protocol exists; state if and where it can be accessed (e.g., a Web address); and if available, provide registration information, including the registration number.	4-5
Eligibility criteria	6	Specify characteristics of the sources of evidence used as eligibility criteria (e.g., years considered, language, and publication status), and provide a rationale.	5
Information sources*	7	Describe all information sources in the search (e.g., databases with dates of coverage and contact with authors to identify additional sources), as well as the date the most recent search was executed.	4-5
Search	8	Present the full electronic search strategy for at least 1 database, including any limits used, such that it could be repeated.	4-5
Selection of sources of evidence†	9	State the process for selecting sources of evidence (i.e., screening and eligibility) included in the scoping review.	4-5
Data charting process‡	10	Describe the methods of charting data from the included sources of evidence (e.g., calibrated forms or forms that have been tested by the team before their use, and whether data charting was done independently or in duplicate) and any processes for obtaining and confirming data from investigators.	4-5
Data items	11	List and define all variables for which data were sought and any assumptions and simplifications made.	5-7
Critical appraisal of individual sources of evidence§	12	If done, provide a rationale for conducting a critical appraisal of included sources of evidence; describe the methods used and how this information was used in any data synthesis (if appropriate).	5-7
Synthesis of results	13	Describe the methods of handling and summarizing the data that were charted.	5-7

SECTION	ITEM	PRISMA-ScR CHECKLIST ITEM	REPORTED ON PAGE #
<b>RESULTS</b>			
Selection of sources of evidence	14	Give numbers of sources of evidence screened, assessed for eligibility, and included in the review, with reasons for exclusions at each stage, ideally using a flow diagram.	8, Tables 1-3
Characteristics of sources of evidence	15	For each source of evidence, present characteristics for which data were charted and provide the citations.	Tables 1-3
Critical appraisal within sources of evidence	16	If done, present data on critical appraisal of included sources of evidence (see item 12).	Tables 1-3
Results of individual sources of evidence	17	For each included source of evidence, present the relevant data that were charted that relate to the review questions and objectives.	8-13
Synthesis of results	18	Summarize and/or present the charting results as they relate to the review questions and objectives.	8-13; figures 1-5
<b>DISCUSSION</b>			
Summary of evidence	19	Summarize the main results (including an overview of concepts, themes, and types of evidence available), link to the review questions and objectives, and consider the relevance to key groups.	14-17
Limitations	20	Discuss the limitations of the scoping review process.	17-18
Conclusions	21	Provide a general interpretation of the results with respect to the review questions and objectives, as well as potential implications and/or next steps.	18
<b>FUNDING</b>			
Funding	22	Describe sources of funding for the included sources of evidence, as well as sources of funding for the scoping review. Describe the role of the funders of the scoping review.	18

JBI = Joanna Briggs Institute; PRISMA-ScR = Preferred Reporting Items for Systematic reviews and Meta-Analyses extension for Scoping Reviews.

\* Where *sources of evidence* (see second footnote) are compiled from, such as bibliographic databases, social media platforms, and Web sites.

† A more inclusive/heterogeneous term used to account for the different types of evidence or data sources (e.g., quantitative and/or qualitative research, expert opinion, and policy documents) that may be eligible in a scoping review as opposed to only studies. This is not to be confused with *information sources* (see first footnote).

‡ The frameworks by Arksey and O'Malley (6) and Levac and colleagues (7) and the JBI guidance (4, 5) refer to the process of data extraction in a scoping review as data charting.

§ The process of systematically examining research evidence to assess its validity, results, and relevance before using it to inform a decision. This term is used for items 12 and 19 instead of "risk of bias" (which is more applicable to systematic reviews of interventions) to include and acknowledge the various sources of evidence that may be used in a scoping review (e.g., quantitative and/or qualitative research, expert opinion, and policy document).

## Abstract

**Objectives:** Our objective was to review the literature on the inferred duration of the infectious period of COVID-19, caused by SARS-COV-2 virus, and provide an overview of the variation depending on the methodological approach.

**Design:** Rapid scoping review. Literature review with fixed search terms, up to 1<sup>st</sup> April 2020. Central tendency and variation of the parameter estimates for infectious period in (a) asymptomatic (b) symptomatic cases from (i) virological studies (repeated testing), (ii) tracing studies (iii) modelling studies were gathered. Narrative review of viral dynamics.

**Information sources:** Search strategies developed and the following searched: PubMed, Google Scholar, MedRxiv, BioRxiv. Additionally, the Health Information Quality Authority (Ireland) viral load synthesis was utilised, which screened literature from PubMed, Embase, ScienceDirect, NHS evidence, Cochrane, medRxiv and bioRxiv, HRB open databases.

**Results:** There was substantial variation in the estimates, and how infectious period was inferred. One study provided approximate median infectious period for asymptomatic cases of 6.5-9.5 days. Median pre-symptomatic infectious period across studies varied over <1-4 days. Estimated mean time from symptom onset to two negative RT-PCR tests was 13.4 days (95%CI: 10.9-15.8), but was shorter when studies included children or less severe cases. Estimated mean duration from symptom onset to hospital discharge or death (potential maximal infectious period) was 18.1 days (95%CI: 15.1–21.0); time to discharge was on average 4 days shorter than time-to-death. Viral dynamic data and model infectious parameters were often shorter than repeated diagnostic data.

**Conclusions:** There are limitations of inferring infectiousness from repeated diagnosis, viral loads, and viral replication data alone, and also potential patient recall bias relevant to estimating exposure and symptom onset times. Despite this, available data provides a preliminary evidence base to inform models of central tendency for key parameters, and variation for exploring parameter space and sensitivity analysis.

## Strengths and limitations of this study

- A comprehensive overview of the literature pertaining to inferred infectious duration of COVID-19, including indirect measures from virological, contact tracing, and modelling studies to 1<sup>st</sup> April 2020.
- Both narrative review and quantitative analysis presented

- 50 • Small number of comparable parameter estimates for meta-analysis is a limitation
- 51 • Much of the current research material on COVID-19 is from preprint papers, and therefore
- 52 have not gone through formal peer review

For peer review only

## 53 Introduction

54 Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), a new coronavirus, emerged in  
55 China in late 2019.[1,2] The virus causes COVID-19, a disease characterized by variable, mainly  
56 respiratory, symptoms across cohorts, from asymptomatic cases through to mild (for example, dry  
57 cough, fever) and severe cases (for example, pneumonia).[3,4] The severity of symptoms, and their  
58 clinical outcome, have been reported to vary by age-class and whether patients have underlying  
59 comorbidities. The case-fatality rate increases with age, and are highest for those above 70  
60 years.[5,6] There are several cases of asymptomatic test-positive patients reported in the emerging  
61 literature (e.g. [4,7,8]). Furthermore, asymptomatic (and pre-symptomatic) cases have been shown  
62 to be infectious, and secondary cases have been reported.[9,10] However, the duration of this  
63 infectious period is difficult to measure accurately, and the time course of the natural history of  
64 infection generally must be inferred indirectly, via contact tracing of cases, serial repeated diagnostic  
65 virological studies, and/or through modelling approaches. Symptomatic cases can experience an  
66 infectious pre-symptomatic period before the onset of symptoms, therefore understanding the  
67 whole infectious period for this cohort requires estimating the duration of both periods. It is  
68 essential to rapidly gain insight into this key variable impacting our understanding of COVID-19  
69 epidemiology. Anderson et al. [11] point out one of the “key unknowns” is the infectious period for  
70 COVID-19, which they suggest may be 10 days but subject to great uncertainty.

71 Here we gathered data from published research from peer-reviewed and preprints from 1<sup>st</sup>  
72 December to 1<sup>st</sup> April 2020, to characterize the variation in the infectious duration inferred from the  
73 three lines of evidence. We also provide a narrative review of the viral dynamic literature. Our focus  
74 was on duration, relative infectiousness has been dealt with elsewhere [12,13]

75 The aim of this review was to provide an overview and critical appraisal of published and preprint  
76 articles and reports that assess or quantify the inferred duration of the infectious period in order to  
77 best parameterise COVID-19 epidemiological transmission models.

**Materials and Methods**

***Conceptual model of population infection dynamics***

Infectious period was contextualised in relation to a working conceptual model of COVID-19 disease dynamics (Figure S1, supplementary material 1). From this conceptual model, three parameters were identified as important in context of this study:

T2, defined as: Duration of the total infectious period for asymptomatic cases, post-latent to recovery [‘recover’ in this context relates to clearing of infection]

T3, defined as: Duration of pre-symptomatic infectious period for those infected individuals who subsequently develop symptoms (that is, post-latent to onset of symptoms)

T5, defined as: Duration from onset of symptoms to recovery\* or death.

\* recovery was inferred as either the first of two clear RT-PCR tests, or hospital discharge after admission from COVID-19 related symptoms.

“Asymptomatic” case definition was interpreted pragmatically following Davies et al. [14,15], and may include very mild symptoms that may occur but are unnoticed.

T2, T3, T5 represent readily measurable parameters, but may be upper limits of infectious period, as patients may be non-infectious for a period before recovery or death. We also review evidence where infectiousness is inferred from viral shedding and contract tracing [transmission], see below.

***Literature search***

A survey of the literature between 1<sup>st</sup> December 2019 and 1<sup>st</sup> April 2020 for all countries was implemented using the following search strategy. Publications on the electronic databases PubMed, Google Scholar, MedRxiv and BioRxiv were searched with the following keywords: “Novel coronavirus” OR “SARS-CoV-2” OR “2019-nCoV” OR “COVID-19” AND “infectious”. Additionally, national and international government reports were monitored. No restrictions on language or publication status were imposed so long as an English abstract was available. Articles were evaluated for data relating to the aim of this review; all relevant publications were considered for possible inclusion. Bibliographies within these publications were also searched for additional resources.

Manual searches of the literature was undertaken using daily updated COVID19 collections from the National Centre for Biotechnology Information (NCBI) and MedRxiv servers (<https://connect.medrxiv.org/relate/content/181>), respectively, searching specifically for papers relating to “infectious period” or “infectious duration” from both empirical and modelling studies.

Finally, we utilised the complementary work undertaken by the Health Information and Quality Authority (HIQA) of Ireland, specifically the evidence summaries relating to asymptomatic transmission and viral load [16,17]. The protocol for the evidence synthesis is published on the HIQA website [18]. Briefly, the evidence synthesis process included searching databases from 30<sup>th</sup>

December 2019 to 27<sup>th</sup> March 2020 (PubMed, Embase, ScienceDirect, NHS evidence, Cochrane, medRxiv and bioRxiv, HRB open), screening, data extraction, critical appraisal and summarizing the evidence.

Our aim was to have as great a breadth for an evidential base as possible, to clarify what evidence was available to inform on the infectious period of COVID19, and to identify key characteristics of the data sources and their interpretation. Therefore, our approach is a scoping review (following [19]). However, due to the emergent nature of COVID-19, this work is considered a rapid review.[20] This paper follows the Preferred Reporting Items for Systematic Reviews and Meta-Analyses—Extension for Scoping Reviews (PRISMA-ScR) checklist. In accordance with the PRISMA-ScR checklist, the electronic search strategy can be found in the supplementary material (Supplementary material 2).

Inclusion criteria were for papers that provided data to inform duration of infectious period based on: time from symptoms to recovery; time from symptoms to death; time from symptoms to diagnostic test clearance [ $\geq$ two clear tests, defined as at least two consecutive negative reverse transcriptase polymerase chain reaction (RT-PCR) tests conducted 24 hours apart]; pre-symptomatic infectious period; time from first diagnostic test to diagnostic test clearance [ $\geq$ two clear tests] for pre-symptomatic/asymptomatic cases. Inclusion criteria for viral dynamics, were papers which reported viral load via cycle threshold (Ct) values from RT-PCR testing over repeated sampling of infected patients, and studies that additionally reported viral isolation.

For quality control, studies were (i) selected and screened initially by three members of the team from search terms outlined above (ÁBC, KH, FB), with parameters identified and recorded. (ii) This was reviewed and supplemented by manual search by a different two team members (AWB, DM), again with parameters identified and recorded. (iii) Finally, the review was then internally reviewed by an additional two members of the team (CMC, MC), and cross-referenced with other parameter synthesis documents being worked on by the group (*all authors*).

## ***Parameter comparison***

### ***Parameters of interest***

1. *A-priori* it was decided to harvest parameter estimates for (i) asymptomatic, and (ii) symptomatic cases. As the period of infectiousness can only be estimated indirectly, parameter estimates from the literature was gathered from three different methodological approaches: Virological studies tracking patients overtime undertaking serial testing, where infectious period was inferred from diagnostic testing history and/or by virus isolation.

- 2. Contact tracing studies where infectiousness is inferred by infector-infectee histories and/or clusters of infection.
- 3. Model parameters entered into mathematical models [priors] representing explicitly infectious periods, or model parameters estimated from mathematical models [posterior estimates] estimating explicitly infectious periods

Visual and quantitative comparisons

To compare parameters visually, simulated distributions were estimated from the central tendencies and variation metrics described in the primary literature. To simulate data, 10,000 random variates were drawn from random number functions in Stata (ME, version 15.1; StataCorp. 2017. Stata Statistical Software: Release 15. College Station, TX: StataCorp LLC) [rnormal, rgamma]. Where possible, the distribution reported within the primary literature was used to represent the distribution (e.g. Gaussian, Gamma). Where distributional data could not be inferred, point estimates were presented.

There were adequate comparable data gathered on the duration of T5 (duration from onset of symptoms to death or recovery) from virological studies to employ a meta-analytic model. Many of the studies report different central tendency estimates, including mean and median. Methods of reporting variation across this central tendency included standard deviation, range, inter-quartile range. To facilitate meta-analysis, reported estimates from all studies were converted to the mean and standard deviations based on the formulae given in Wan et al. [21].

To obtain the standard deviations from 95%CI, the method outlined in the Cochrane handbook [22] was used:

$$SD: \sqrt{n}(\text{Upper limit of CI} - \text{Lower limit of CI})/3.92$$

Standard Error (SE) was calculated from Standard Deviation (SD) and sample size (n), using:

$$SE = SD/\text{SQRT}(n)$$

Comparisons were made using the METAAN package in Stata 15, using the random-effects (DerSimonian-Laird) model.[23] This model assumes heterogeneity between the studies; that is, it assumes that the true effect can be different for each study. The model assumes that the individual-study true effects are distributed with a variance  $\tau^2$  around an overall true effect, but the model makes no assumptions about the form of the distribution of either the within-study or the between-

176 studies effects. Weightings were derived from the standard error [precision] around the estimate.  
177 Comparisons were presented as forest plots. Heterogeneity between studies was tested using  
178 Cochran's Q; the magnitude of the heterogeneity was categorised using  $I^2$  as high (>75%), moderate  
179 (50-75%), or low (<50%).[24]

180 Variation in duration across T5 virological studies was compared using a random effects meta-  
181 regression model, using the METAREG command in Stata 15.1. The hypothesis that heterogeneity  
182 may be related to the inclusion of children or depending on symptom severity within the sample,  
183 was tested in separate univariate models. Severity was dichotomised (0/1) into studies that included  
184 patients described as having 'mild' or 'mild-moderate' symptoms, versus studies that included  
185 patients with 'moderate-severe' or 'severe' symptoms. Similarly, studies were categorised into  
186 having some samples from "children" (as reported in the paper), or wholly adult samples. These  
187 variables were then fitted as a dichotomous dummy predictor [independent]. The parameter  
188 estimates from the regression model was solved using restricted maximum likelihood (REML);  
189 additionally, p-values were estimated using a Monte Carlo model with 1000 permutation test.[25]

190 Raw patient-level data were available from three studies in relation to time from onset to hospital  
191 discharge or death (potentially inferring maximal T5 duration). To estimate the predicted mean and  
192 95%CI duration across these studies, data were analysed using a Gaussian random effects model  
193 (using XTREG command, Stata 15), with study categories fitted as the RE. A linear regression model  
194 with 'study' fitted as a categorical dummy variable was used to estimate the difference between  
195 duration across study datasets. Code and data are provided in Supplementary Material 3 & 4.

### 196 ***Viral dynamics***

197 A narrative comparison of reported viral dynamics from studies that undertook serial viral load  
198 estimates from patients over their period of observation was undertaken. Trends in the literature,  
199 strength and weaknesses were identified, and a conceptual model illustrated.

**Results**

***Parameter comparison***

Overall, 65 parameter estimates were harvested from 48 papers (Tables 1, 2, 3).

*Infectious period for asymptomatic cases (T2)*

The overall distributions and point estimates from studies for T2 are presented in Figure 1 and Table 1.

Two virological studies reported on infectious period based on serial diagnostic testing, for asymptomatic cases, were found to have informative data. One of these studies reported on only one asymptomatic case, with exposure to negative tests being 11 days (Table 1). This duration should be considered an over-estimate, given that a latent period is not taken into consideration. Hu et al. [7] tracked infections of close contacts to infected persons and considered patients asymptomatic at time of diagnosis. Infectious period was defined as time from diagnosis to the first of two clear tests, providing a median duration of 9.5 days (n=24) range: 1 – 21; 3.5-13.0 IQR.

Importantly, Hu et al. [7] found that the infectious period was different between those who subsequently exhibited symptoms (i.e. pre-symptomatic) and those who did not: The median duration for asymptomatic infectious was 6.0 days (IQR: 2.0 - 12.0; N=19). This was reduced to 4.0 days (2.0 - 15.0) for cases that were asymptomatic without abnormal computed tomography (CT) scans (n=7).

Two tracing studies provide informative data (Table 1; [7,8]). Infectious period was inferred indirectly from data provided in Ma et al. [8], whereby infectious period was estimated as the difference between the upper (maximal) latent period estimate minus the serial interval. Ma et al. [8] reports on 49 asymptomatic cases and inferred serial interval from infector-infectee pairs. Serial interval was calculated by assuming “onset” was at first diagnosis. Hu et al. [7] reported on a case-study cluster of infection within a house where the primary case was asymptomatic. Secondary infections occurred 4-9 days after index case exposure, the index patient tested positive until day 29 post exposure.

Modelling studies that have attempted to fit differing parameters depending on the severity of symptoms have used differing nomenclature, for example asymptomatic, “mild” or subclinical cases (Table 1).[14,15,26,27] Two papers by Davies and colleagues [14,15] model this parameter as a gamma distribution with a mean periods of 5-7 days (Fig. 2); importantly, these papers assume infectious period is the same for asymptomatic and symptomatic cases.

### 231 Pre-symptomatic, infectious period (T3)

232 Pan et al. [3] and Hoehl et al. [28] describe the cases of two individuals tracked and serially tested by  
 233 real-time reverse transcriptase polymerase chain reaction (RT-PCR) after being exposed to a patient  
 234 with confirmed infection. In the latter study, the virus was isolated from samples, indicating  
 235 transmission potential.

236 Four studies from China, Germany and Singapore provide informative data through tracing infections  
 237 from cluster of infections, and through infector-infectee pairs (Table 2).[4,9,29,30] These papers  
 238 included the study by Rothe et al. [9], which clarified that an asymptomatic patient visiting Germany  
 239 from China may have actually experienced very mild symptoms around the time of transmission  
 240 occurred (see discussion).

241 Five modelling papers incorporated pre-symptomatic infectious period reported as prior  
 242 distributions or estimated as a model output. Two papers describe the prior distribution using a  
 243 gamma distribution.[14,15] Tindale et al. [31] provide mean point estimates under four different  
 244 scenarios (two populations, early and late epidemic period). Peak et al. [32] derives estimates of the  
 245 pre-symptomatic infectious duration from a model of serial interval, and report scenarios where  
 246 there are pre-symptomatic infectious periods.

247 The approximated distributions are simulated in Figure 2, which demonstrates the between-study  
 248 heterogeneity in this parameter. The point estimates primarily cluster around the central tendencies  
 249 of the distributions, except for Tindale et al. [31], for a model reporting for late occurring cases in  
 250 Tianjin, China (8.2 days).

### 251 Post-symptom onset, infectious period (T5)

252 The T5 parameter was informed from three lines of evidence from empirically driven studies:

- 253 • time from symptoms onset to the first of two clear RT-PCR tests
- 254 • time from symptoms to hospital discharge
- 255 • time from symptoms to death

256 Figure 3 presents the forest plot for the mean time from symptom onset to clearance, based on  
 257 serial testing meta-analysis (n=15). The mean estimated duration was 13.4 days (95%CI: 10.9-15.8).  
 258 There was high heterogeneity across studies (Cochrane's Q;  $p < 0.001$ ;  $I^2 > 75\%$ ). A random effects (RE)  
 259 meta-regression model suggested significant variation depending on whether studies included  
 260 children as part of the sample (n=15 studies; Proportion of between-study variance explained  
 261 Adj.  $R^2 = 43.8\%$ ). Overall, the model estimated studies including children had on average 5.8 days

shorter duration than adult only studies (95%CI: 1.7-10.0;  $p=0.040$ ;  $SE(p)=0.003$ ). A second univariate RE meta-regression model suggested that there was non-significant increased mean duration of 4.0 days (95%CI: -0.6-8.6;  $p=0.111$ ;  $SE(p)=0.005$ ; Adj.  $R^2 = 22.0\%$ ;  $n=14$ ) for studies that included moderate-severe or severe cases, relative to mild or mild-moderate severity cases.

High transmissibility during the first 5 days post symptom onset was described by Cheng et al. [33], based on secondary attack rates for 12 infector-infectee pairs. No contacts ( $n=1043$ ) with primary cases were infected after five days of the index case onset of symptoms, inferred by the authors to suggest transmission occurring at symptom onset (but conceivably also suggest pre-symptomatic infection). Based on a cumulative density function, the authors suggest that infectiousness declines rapidly from onset of infection (distribution was truncated at 30 days); estimated cumulative infectiousness was 66.9% (95%CI: 28.7-94.8) by day 1, and reached 86.9% (95%CI: 64.3-99.5) by day 5 post-symptom onset (Figure S2).

For tracking studies relating to time to hospital discharge or death, raw case level data were available (studies  $n=3$ ). [31,34–36] Histograms of the raw data are presented in Figure 4, along with the aggregated distribution. A random effect model suggested a mean duration of 18.1 days (95%ci: 15.1 – 21.0). However, there was significant variation across studies, with time to discharge being 4.96 days shorter (95%CI: 2.15- 7.76; [35]), or 3.79 days shorter (95%CI: 0.8-6.7; [31]), than time-to-death [34].

Two modelling papers use priors (mean: 3.2-3.5 days) to represent clinical infectious period.[14,15] However, the distribution for this parameter is right censored when patients are hospitalised or isolated and therefore not an estimate of the full infectious period *per se*.

#### Infectious period for symptomatic cases (T3+T5)

Two tracing studies supplied parameter estimates for the full infectious period for patients who develop symptoms. [8,29] He et al. [29] inferred from a publicly available dataset of 77 infector-infectee pairs that infectiousness began 2.3 days (95% CI, 0.8–3.0 days) prior to symptom onset, peaking at 0.7 days (95% CI, -0.2–2.0 days), and continued up to 7 days from onset. The authors suggest that the transmission risk diminishes 7 days post symptom onset. This suggests that the average infectious period, assuming a symptomatic infectious period of 7 days was approximately 9.3 days (7.8-10 days 95%CI, where CI is only reported for the pre-symptomatic period). He et al. [29] estimated that the proportion of all transmission that was pre-symptomatic was 44% (95% CI, 25–69%). Ma et al. [8] analysed data from a number of countries (China, Germany, Japan, Malaysia, Singapore, Vietnam), collating 1155 cases from public data. They estimate several parameters,

including “maximum latent period” and the serial interval. The authors estimated the infectious period as maximum latent period minus the serial interval. Given their parameter estimates and methodological approach, infectious period would have been 5 days (range 0-24; IQR: 2-9; calculated from data presented within the paper).

Seven modelling papers reported duration of infectious period ( $T_3+T_5$ ; Table 4), with the reported central tendency for the distribution varying from 3-20 days. The form of the distribution offered to models for this parameter varied considerably, including point estimates (deterministic models), flat (uniform), Gaussian, Weibull and gamma distributions. Li et al. [27] estimated the shortest median duration of 3.45 days, with a flat (uninformative) prior distribution corralled between 3-5 days. In contrast, Zhu et al. [37] used a mean prior of 10 days, with the model estimated mean duration being 12.5 days (variance 10; Weibull distribution). Piccolomini and Zama [38] used a fixed estimate of 20 days infectious period, to model the Italian epidemic. Two papers from the same group [14,15] suggested that infectious period for asymptomatic cases approximated for symptomatic cases where there was no right censoring (that is, transmission being halted through isolation or hospitalisation; gamma distributions of mean 5 or 7 days). Tuite et al. [26,39] also assumed the same duration for “mild” and “severe” symptomatic cases (6-6.5 days).

***Viral load dynamics***

Viral load was reported from 21 papers using real-time reverse transcriptase polymerase chain reaction (rRT-PCR) testing, generally post-symptomatic monitoring.[3,29,40–59] Qualitatively, the viral dynamics described early increase in viral load, peaking around onset or within 2-4 days of symptom onset (Figure 5 for a theoretical model), before decreasing gradually over the next one to three weeks post symptom onset. Maximum duration of detection ranged from approximately 20-49 days, with the longest duration associated with faecal samples (see below for discussion). The duration where ribonucleic acid (RNA) was recoverable by RT-PCR may have been truncated due to insufficient follow-up in some cases. Studies that have investigated blood samples have provided some evidence for an association with severity of infection [16,60], though it is not clear whether this is a consistent feature of SARS-CoV-2 infection [40].

It should be noted the lack of data on pre-symptomatic or asymptomatic cases with regards viral load. An exception was Kam et al. [61] who describe a pre-symptomatic case in an infant. In another study, Zou et al. [53] undertook serial RT-PCR testing from nasal and throat swab samples from 14 imported cases, and 4 secondary cases, in Guangdong, China. The dynamics of the infection in terms of cycle threshold (Ct) values and RNA copy number were described; Ct values of 30.76, 27.67, 24.56, and 21.48 corresponding to  $1.5 \times 10^4$ ,  $1.5 \times 10^5$ ,  $1.5 \times 10^6$ , and  $1.5 \times 10^7$  copies per milliliter. Hence, lower Ct values infer higher viral loads. The authors report on a patient without symptoms, but with positive nasal swabs (Ct values, 22 to 28) and throat swabs (Ct values, 30 to 32) testing positive on days 7, 10, and 11 after contact. Importantly, the authors suggest “the viral load that was detected in the asymptomatic patient was similar to that in the symptomatic patients.”

Furthermore, Kimbell et al. [62] report that Ct values between asymptomatic (21.9 to 31.0), pre-symptomatic (15.3 to 37.9), and symptomatic cases (18.6 to 29.2) within a nursing home environment did not differ significantly. To et al. [59] present data on temporal profile of viral load from saliva samples, and found that median initial and peak viral loads in severe cases were non-significantly higher ( $p>0.5$ ) by approximately 1 log<sub>10</sub> higher than those in mild cases. Liu et al. [58] present data showing viral load being 60 times greater for severe cases relative to mild cases.

This lack of pre-symptomatic data may result in left truncation of the risk distribution associated with viral load and shedding. Therefore, the typical timing of peak viral shedding (whether prior to, at, or after onset), and it’s impact on transmission, is still uncertain. He et al. [29] reported highest viral load at symptom onset from patients sampled in a hospital in China. Furthermore, the author’s estimate using a separate infector-infectee dataset (n=77) that 44% (95% CI: 25–69%) of infectee cases were infected during the pre-symptomatic stage of the infector. Separately, a modelling paper

344 by Ferretti et al. [63] also appears to support this, estimating that 47% (0.9/2) of total transmission  
345 contributing  $R_0$ , an overall measure of transmission during an infection, was pre-symptomatic (also  
346 see [33]).

347 Wölfel et al. [50] provides important data on a cohort of nine 'mild' cases which were serially tested  
348 using sputum, swabs (throat and nasopharyngeal), urine and faecal samples over time. Importantly,  
349 the virus was isolated, and inferences on viral replication could be made. Viral Isolation, and insights  
350 into viral replication, improve inference around viral dynamics and transmission risk. The study  
351 suggested high viral loads shortly after symptom onset, which declined thereafter over time. Positive  
352 cultures were found from day 3-8 post-symptom onset (Figure S3), and the minimum 5% isolation  
353 success was achieved up to 9.8 (95% CI: 8.5-21.8) days post onset from throat and lung samples but  
354 not faeces, blood or urine.

**Discussion**

Inferring infectiousness was challenging given the heterogeneity of evidence available. Virological diagnostic studies provide robust time series of infection, however, is limited by inferring the relationship between PCR diagnostics and infectiousness. These data can also be affected by sampling procedure and sample sites (e.g. upper respiratory, lower respiratory, faeces, urine, blood). We have excluded RT-PCR durations based on faecal sampling due to the current uncertainty whether these data pertain to transmission potential ([50]; see below). Virological studies where culturing has taken place, and where viral replication can be inferred would also be considered superior data to infer infectious period, relative to estimates of viral load alone.[50] Where this has taken place, the data would suggest average infectious periods of up to 9.8 days post-symptoms. Recent modelling work suggest that the duration of viral detectability could overestimate the infectious period somewhere between 2-6 days.[64]

Viral load studies suggest peak viral load occurs close to symptom onset (potentially, -1 to 7 days of onset), however there is uncertainty whether this typically occurs prior to, on, or after onset (Figure 5 for conceptual model). High viral loads, measured as Ct values, have been recorded for one week to 20 days post symptom onset, with a general decreasing trend with time. For example, To et al. [59] estimates a declining slope per day for log10 RNA copies per ml of -0.15 (95% CI -0.19 to -0.11;  $R^2=0.71$ ). There are some studies reporting associations between viral load and symptom severity, with higher metrics of viral load in severe cases.[3,58,59] However, Zou et al. [53], and more recent data from Italy,[64,65] suggest similar viral loads in symptomatic and asymptomatic cases.

We tested the hypothesis that severity of symptoms had an effect on symptomatic infectious duration using a meta-regression approach. There was a trend towards studies that included severe cases tended to have longer duration (estimated to be 4.0 days longer), but the effect was not significant. Some studies have reported an association between duration of infectiousness and severity (e.g. [58]). But uncertainty of whether this is robust remains. Caution is required when comparing severity of symptoms, as objective or standardised metrics are not always reported.

Virological studies that included children (either mixed adult children, or children only cohorts) appeared to have shorter T5 durations (estimate: 5.8 days shorter). Liao et al. [66] present data which suggests that children and ‘young adults’ (<35 years old) infected cases exhibited long incubation time (exposure to symptom on-set; mean 7.2 days), and short serial interval (mean 6.5 days; median 1.9 days; time from onset in primary to onset in secondary case).

Contact tracing studies provided robust evidence of transmission events, and therefore infectiousness, but can be limited by the inferred timing of events, and symptoms experienced, due to the self-reported nature of data collection (recall bias). The subjective nature of self-reporting indeed can have an impact on case definitions of 'asymptomatic', which has led to some doubt on asymptomatic transmission in one case.[9] Rothe et al. [9] describe a case of apparent asymptomatic transmission from a Chinese visitor to business associates in Germany, which was cast into doubt when health officials reported that the patient had indeed experienced some, albeit minor, symptoms.[67] Rothe et al. [9] subsequently updated the clarification of the patients self-reported symptoms during the presumed asymptomatic infectious period, which included "feeling warm" and "feeling cold". However, the patient only "recognized getting sick" after she returned to China on day four after the presumed exposure event.

Modelling parameters provide information on how COVID-19 data are being used and interpreted in the research community, given the limited data available. Posterior estimates also provide information on the parameter space at which infectious period central tendency reside, given other parameters and assumptions in the model. Models used highly varied approaches to modelling infectious period, which in turn resulted in highly variable parameter estimates used to inform the studies. An important factor to consider when comparing parameter estimates between empirical and modelling studies is the interpretation of the parameter by different disciplines, and even between researchers from the same discipline. The infectious period can be considered significantly context specific and dynamic, and the ability to transmit infection can be modulated by interventions (e.g. through isolation or hospitalisation). Modelling papers, depending on the model structure, can report truncated infectious period accounting for such interventions. Such estimates are not comparable with our definition of the parameters reviewed, and we have attempted to avoid such disparities where we found them.

#### *Overall duration findings*

There are few data for the precise definition of the asymptomatic infectious period (T2) parameter. Some reported asymptomatic cases can actually be pre-symptomatic, when cases are subject to follow-up (e.g.[66]; see discussion above). However, Hu et al. [7] do provide the data for asymptomatic cases [that remain asymptomatic] across their presumed infectious period. Therefore, in the first instance a parameter mimicking their data is probably the best available data over the period of the present study. Note, there is a large variation in this data parameter, and a gamma distribution of a shape alpha 3, beta 2, mean 6, may be appropriate for the initial model runs. Despite these being the primary informative data, caution is required, given the uncertainty around

the relationship between RT-PCR results and infectiousness. Overall, an informed central tendency of ~6 days, with very low probability draws for durations >20 days for the T2 parameter may be considered given the current state of knowledge.

The pre-symptomatic period is sometimes referred to as ‘preclinical infectious’ period (parameter T3). This has been estimated from several papers, and the central tendency of these estimates vary from <1 - 4 days, cautiously approximating to 2 days, on average. Current models have used central tendency estimates of 0.5 to 2.4 days.[14,15,26,39] The relative consistency around the duration of this period allows for some confidence of its distribution. Current understanding of viral dynamics of infection suggest that viral load and shedding increases during post-latent phase, peaking around onset [for symptomatic cases], before declining.[29,50,53] This aspect of the natural history of infection may be important when attempting to model transmission dynamics.

Length of infectious period in symptomatic cases that do not isolate (T5 parameter) has also been rarely directly measured in the literature, as serial monitoring of patients in terms of symptoms or viral load (rt-PCR) generally occurs after diagnosis and/or after admission to hospital [from a modelling perspective, this means cases are censored as they are assumed to no longer contribute to transmission]. If natural progression of infection after diagnosis or hospital admission mimics the course of infection for those who do not isolate, the review of the literature describing time to two clear tests is informative. Symptom onset to serial testing clearance [assessed the time to first of two RT-PCR clear tests] averaged 13.4 days from our meta-analysis. In the maximal case, where patients succumb or fully recover from infection, time from symptoms to death or discharge may be informative. Studies that collated such information suggest mean durations of 18.07 days, but with time to discharge being 4.96 days shorter on average than time to death. These values may represent an over estimation of the infectious period; one study suggested that there was on average 2.5 days between end of infectiousness and ‘removal’ (recovery or death).[37]

Cheng et al. [33] provided evidence of transmissibility, based on attack rate from primary to secondary cases, at around symptom onset. The authors estimate cumulative infectiousness from onset, which suggests that 67% of total infectiousness potential occurs by the first day post-onset. Most of the total infectiousness occurs within 5 days (86.9%) post onset, with the remaining infectiousness potential (13.1%) being distributed up to day 30 (this truncation is an assumption by the authors). It is possible that pre-symptomatic transmission occurred during this study, but the authors do not estimate what proportion of transmissions occurred during a pre-symptomatic infectious period, or its potential duration.

A model by He et al. [29] is informative for overall symptomatic duration (T3+T5), using 77 infector-infectee pairs where COVID-19 transmission occurred in China. The study reported that infectiousness was apparent on average 2.5 days prior to symptoms, reached a peak in risk at 0.6 days before symptoms, and decline up until 7 days after onset (9.5 days total infectious period). The proportion of transmission before symptom onset (area under the curve) was estimated as 44% (95% CI, 25–69%), based on inferences on incubation period. The authors suggest their data supported the view that transmission risk decline substantially after 7 days post-symptoms onset.

Model estimates used for infectious period parameter appears to be shorter than virological studies tracking RNA viral load over time. For example, Liu et al.[27] fitted a flat prior distribution for mean duration ( $D$ ) fixed to vary between:  $2 \leq D \leq 5$  days, and Lavezzo et al. [64] fixed infectious period to 2 days in their epidemic model; whereas viral repeat testing studies provide evidence to suggest high viral loads can be detected to up 20 days (e.g. pharyngeal swabs), and potentially longer from faecal samples (up to 3-4 weeks post symptoms onset)). Oral-faecal transmission risk is currently unknown, but some doubt has been raised about studies that have reported positive RTPCR test results (see [68]; but there may be some evidence of the risk amongst children; [69]). Wölfel et al. [50] has produced an important study that provides some data on viral replication, and the site and duration over which this may be taking place. Their data suggests that viral replication, with high viral loads, occur in the upper respiratory tract, over the first week of symptoms peaking in day 4. Virus could not be isolated from faecal samples, despite high RNA concentration. Furthermore, virus was not isolated from blood or urine in that study.[50]

It should be noted that some of the virological and tracing studies reviewed had small sample sizes (see Study Limitations) and potentially biased towards more severe cases or clusters of infection. It is unknown as to whether these cases are representative of infectious duration generally across populations. However, if symptom severity is linked to infectious duration, one could speculate that this bias could help to explain the some of the difference between model and empirical duration estimates.

### Study limitations

Overall, the studies included were of good quality, though due to the rapid need for information from the global research community many papers are pre-prints that have yet to be reviewed (at time of writing). Many papers were limited in terms of sample sizes, with several papers being case studies of one patient or single cluster outbreaks. There was a diversity of methods employed to infer dynamics of infectiousness across studies, and therefore the evidential base was variable. Some issues around nomenclature were noted, including definitions of asymptomatic, infectious period,

1  
2  
3 484 latent, and incubation period. It is possible the same data may have been used across different  
4  
5 485 studies, especially where publicly available data were used.  
6  
7 486 There was significant heterogeneity across study findings, and this was related to diversity of clinical  
8  
9 487 findings and methods employed. The meta-analysis employed for one parameter (T5) using  
10  
11 488 virological studies, where cross study comparisons could be made, suggested that the heterogeneity  
12  
13 489 was high. Fu et al.[70] cautions against combining studies to give an overall estimate without  
14  
15 490 exploring subgroup or meta-regression analysis, which we have done here. The meta-regression was  
16  
17 491 based on a small number of studies (n=12-13). Cochrane’s handbook suggests 10 studies for each  
18  
19 492 level of a meta-regression, however in practice much lower numbers have been used to test  
20  
21 493 hypotheses [22], as is the case here. Fu et al. [70] recommend a minimum of 4 studies per category,  
22  
23 494 and therefore we dichotomised our predictor variables to ensure we met this minimum. Aggregating  
24  
25 495 our categories resulted in crude findings.  
26  
27 496 Another limitation is that a systematic review was not undertaken to inform this research, hence  
28  
29 497 there is a possibility that some relevant studies were overlooked. However, two independent  
30  
31 498 research groups conducted comprehensive search strategies as part of a broader epidemiological  
32  
33 499 parameters project for COVID-19 [12,13,71,72,73] to inform this research, hence limiting the  
34  
35 500 potential for missing key studies.

36 501 **Conclusion**

37 502 There are few data to inform asymptomatic infectious period (T2 parameter). One study provide  
38  
39 503 data that suggest a median period of 4-9.5 days, however, given the viral dynamics, this distribution  
40  
41 504 could have an extended tail with low probability long infectious periods of up to 20 days. The pre-  
42  
43 505 symptomatic infectious phase (T3) is quite narrowly defined to a mean of approximately 2 days  
44  
45 506 (range: <1-4) within the literature. However, there is great uncertainty around the infectious period  
46  
47 507 from onset to recovery or death (T5 parameter). The symptom onset until clearance (based on two  
48  
49 508 negative RT-PCR tests) parameter estimate of 13.4 days (95%CI: 10.9-15.8) is informative for T5  
50  
51 509 parameter, only if one assumes that RT-PCR positive results equate to having infectious potential.  
52  
53 510 Many current models corral the infectious period to shorter time periods than what virological  
54  
55 511 studies have suggested, with one recent study suggesting that duration of viral detectability over-  
56  
57 512 estimates the infectious period on average by 2-6 days. While viral RNA can be detected for long  
58  
59 513 periods of time, especially from faecal samples, the ability to isolate the virus from Infected cases  
60  
61 514 quickly declines after one-week post-symptoms. Some modelling papers have assumed that  
62  
63 515 infectious period is invariant to whether cases are asymptomatic or symptomatic, however, the data  
64  
65 516 available are not yet rich enough to inform whether this is a good assumption. Similarly, it is not yet

established whether viral loads are similar between asymptomatic and mild, moderate, or severe symptomatic cases, with conflicting reports in the literature.

**Word count:** 5829

**Contributors:** AWB conducted the eligibility screening of shortlisted studies, extracted the data and conducted the analyses, completed the initial draft of the manuscript; SM was involved in conception and project coordination; AC, KH and FB conducted the initial literature searches; DM, KOB, KW conducted searches and screened shortlisted studies; AWB, SM, AC, KH, FB, DM, KOB, KW, AB, JG, EL, PW, CM, MC critically reviewed and commented/edited the paper. All authors read and approved the final manuscript.

**Competing interests:** All authors have completed the ICMJE uniform disclosure form at [www.icmje.org/coi\\_disclosure.pdf](http://www.icmje.org/coi_disclosure.pdf) and declare: no support from any organisation for the submitted work; no financial relationships with any organisations that might have an interest in the submitted work in the previous three years; no other relationships or activities that could appear to have influenced the submitted work

**Funding:** There are no funders to report for this submission.

**Data availability statement:** The data used in this paper and code are presented in Supplementary Material 3 & 4; No additional data available.

**Patient and public involvement statement:** It was not appropriate or possible to involve patients or the public in the design, or conduct, or reporting, or dissemination plans of our research

**Tables and figures**

**Figure 1:** Simulation of the parameter distribution inferred for duration infectious period for asymptomatic cases (T2) inferred infectious period for Davies et al. (2020a), grey/blue curve, Davies et al. (2020b) pink curve [model priors]. Green curve: Ma et al. (2020). Histogram is the distribution of asymptomatic cases to two clear tests reported by Hu et al. (2020). Reference lines are point estimates reported from Zhou et al. (2020), Li et al. (2020), and Tuite et al. (2020a & b).[7,8,14,15,26,27,39,71]

**Figure 2:** Simulation of the parameter distribution used for T3 (the duration of the pre-symptomatic infectious period for those infected individuals who subsequently develop symptoms). Curves represent simulated approximations of distributions, given information provided from primary literature. Vertical lines represent point estimates where distributions could not be inferred (see table 2). 1. Peak et al. [posterior]; 2. Davies et al. 2020b [prior]; 3. Rothe et al. 2020; 4. He et al. 2020; 5. Davies et al. 2020a [prior]; 6. Wei et al. 2020. [9,14,15,29,30,32]

**Figure 3:** Forest plot of the mean duration from onset of symptoms to death or recovery (T5) based on virological studies

**Figure 4:** Frequency distribution of **T5**, time from onset of symptoms to recovery (here hospital discharge or death), using patient level raw data from Kraemer et al. ([35,36]; pink bars), Linton et al. ([34]; purple bars) and Tindale et al. ([31]; green bars). Blue solid line is the kernel density of the aggregated dataset Dashed lines represent the mean and 95%CI from a random effects regression model.

**Figure 5:** Composite inferred model for cycle threshold (CT) value changes from serial RT-PCR testing for SARS-COV2; currently uncertain whether peak viral load typically occurs prior to, on, or post-symptom onset (primary literature informing this model includes [29,50,53,59]).

**Table 1:** Reported infectious period (IP) for asymptomatic cases (T5 parameter) from virological studies where serial diagnostic tests were undertaken to infer IP; tracking studies where IP is inferred from contact tracing; modelling studies where IP is reported as a prior (assumed parameter value) or an posterior estimate.

No.	Study	Countries	Parameter (days)	n	Central tendency reported	Variation (days; inclus.)	Comment
<b><i>Virological studies</i></b>							
[74]	Zhou et al. (2020)	China	11 days	1	Max		This study <b>serially swabbed and tested</b> symptomatic (17) and asymptomatic (1) cases via RTPCR. The single asymptomatic case tested positive up to 11 days post contact with an infected patient (presumed point of exposure).
[7]	Hu et al. (2020)	China	9.5 days	24	Median	1-21 range	<b>Serial testing.</b> Period between “onset” (where onset relates to first positive test) and clearance, adjudged via two negative RTPCR tests, deemed by the authors to be the ‘communicable period’. IQR: 3.5-13
<b><i>Tracking studies</i></b>							
[8]	Ma et al. (2020)	China, Germany, Japan, Singapore, South Korea, Malaysia, Vietnam	7.25 days*	49	Mean	5.91-8.69 (95%CI)	*Ma et al. (2020) does not report infectious period for asymptomatic cases explicitly within their paper. The authors estimated the infectious period as the upper estimated latent period minus the serial interval, using a dataset of 1155 cases from several countries (latent period was estimated with 11 infector-infectee pairs; serial interval was estimated from 689 infector-infectee pairs). Ma et al. (2020) reported a mean upper limit of latent period of 2.52 days; the mean serial interval for asymptomatic cases (using date of diagnosis for onset) was estimated to be 9.77 (94%CI: 8.43, 11.21).

[7]	Hu et al. (2020)	China		3		4-9 range	Cluster of infection within a family, where the primary case was asymptomatic. The transmissions to secondary cases occurred over a period 4-9 days post the presumed point of exposure for the primary case.
<b>Modelling studies</b>							
[27]	Li et al. (2020)	China	3.5* [posterior from a model estimating duration for undocumented cases]		Median	3.19-3.78 95%CI	Li et al. (2020) do not explicitly attempt to model asymptomatic cases, or their infectious duration. Instead the population infected is divided into 'documented' and 'undocumented'. Documented were all cases where patients had symptoms severe enough to be confirmed infected; all other cases were considered undocumented. Therefore, this estimate represents asymptomatic and 'mild' cases. The 95%CI around the median infectious period estimate was 3.19-3.78
[26,39]	Tuite et al. (2020a &b)	Canada	6-6.5 [Prior]		[Fixed parameter within a deterministic model]		Mathematical model [deterministic], with a fixed parameter estimate of 6 or 6.5 days. Important to note that duration for 'mild' was equal to severe cases.
[14]	Davies et al. (2020) (a)	UK	7 days [Prior]		Mean		Model with asymptomatic infection compartment. Modelled with a gamma distribution, beta 1.4; alpha 5. Despite, the subclinical aspect of this parameter, it could be considered analogous to total infectious period without intervention.
[15]	Davies et al. (2020) (b)	UK	5 days [Prior]		Mean		Model with asymptomatic infection compartment. Modelled with a gamma distribution, k=4. Authors: "Assumed to be the same duration as total infectious period for clinical cases, including preclinical transmission"

**Table 2:** Reported infectious period (IP) for pre-symptomatic cases (T3 parameter) from virological studies where serial diagnostic tests were undertaken to infer IP; tracking studies where IP is inferred from contact tracing; modelling studies where IP is reported as a prior (assumed parameter value) or an posterior estimate.

	Study	Location	Parameter (days)	Central tendency reported	Variation (days; inclus.)	Comment
<b><i>Virological studies</i></b>						
[3]	Pan et al. (2020)	Beijing, China	1	Median		Case study of two individuals tracked due to exposure to an infected patient was <b>serially tested</b> prior to onset of symptoms.
[28]	Hoehl et al. (2020)	Flight from Wuhan to Germany	1	Median		Case study of <b>serially tested</b> at risk cohort flying from Wuhan to Germany. Two patients were asymptomatic test positive; additionally virus isolation was achieved, indicating potential infectiousness.
<b><i>Tracking studies</i></b>						
[4]	Huang et al. (2020)	Nanjing, China	4	Median	3-5 range	Follow-up <b>tracing</b> case study cluster of infection within a family demonstrating pre-symptomatic infection (n=10)
[9]	Rothe et al. (2020)	Germany	2	Median	1-3 range	<b>Tracing</b> case study of a cluster of infections whereby pre-symptomatic transmission occurred (n=3).
[29]	He et al. (2020)	Vietnam, Malaysia, Japan, China, Taiwan, USA, Singapore	2.3	Mean	95% CI, 0.8–3.0	<b>Tracing</b> paper infector-infectee pairs. Estimated from serial interval and incubation periods. N=77
[30]	Wei et al. (2020)	Singapore	2.5	Median	2-3 (IQR)	<b>Tracing</b> study investigating pre-symptomatic infections from primary cases to secondary cases in 7 clusters. N=8 primary cases. T3 estimated as the min. days between transmission period (TP) and primary case

						symptom onset, when TP straddled >1 day. Range: 2-6 days.
<b>Modelling studies</b>						
[32]	Peak et al. (2020)	Massachusetts	0.8 [estimate]	Mean	-0.29-1.98 95% CI*	<b>Modelling paper</b> estimated under two scenarios – a serial interval of 4.8 days or 7.5 days. Under scenario one, the model estimated a period of pre-symptomatic transmission (median: 0.71). * the lower range was fixed at zero as the model allowed for no pre-symptomatic infectious case.
[37]	Zhu et al. (2020)	Wuhan, China	1.0 [estimate]	Mean		<b>Modelling paper.</b> Model estimated point value – This is a model derived value
[14]	Davies et al. (2020) (a)	UK	2.4 [prior]	Mean		<b>Modelling paper.</b> Gamma distribution; k=5.
[15]	Davies et al. (2020) (b)	UK	1.5 [prior]	Mean		<b>Modelling paper.</b> Gamma distribution: k=4
[26,39]	Tuite et al. (2020a & b)	Canada	0.5, 1 [prior]	Fixed		<b>Modelling paper.</b> Fixed parameter within a deterministic model.
[75]	Ferguson et al. (2020)	UK	0.5 [prior]	Fixed		<b>Modelling paper.</b> Fixed parameter within this model, whereby infectiousness was assumed to begin 12 hours symptom onset.
[31]	Tindale et al. (2020)	Tianjin, China, and Singapore	2.9-2.6 [estimate]	Mean	1.2-8.2 mean range, depending on early or late cases, or whether in Tianjin, Singapore	Statistical <b>modelling</b> study estimating period pre-symptomatic transmission inferred from estimates of serial interval and incubation periods for populations in Tianjin and Singapore (n=228).

**Table 3:** Reported infectious period (IP) for post-symptomatic cases (T5 parameter) from virological studies where serial diagnostic tests were undertaken to infer IP [onset to  $\geq 2$  tests]; tracking studies where IP is inferred from patient histories from onset to recovery or death; modelling studies where IP is reported as a prior (assumed parameter value) or an posterior estimate.

No.	Study	Location	Parameter (days)	Central tendency reported	Variation (days; inclus.)	Comment
<b>Virological studies</b>						
[76]	Cai et al. 2020 (a)	China	12	Median	6-22 range	<b>Serial testing</b> study of n=10 mild cases RT-PCR confirmed in children. IQR: 8-15 days
[77]	Cai et al. 2020 (b)	China	14	Median	9-19 (IQR)	<b>Serial testing</b> study with n=298 confirmed (RT-PCR) cases treated within hospital setting
[78]	Chen et al.(2020)	China	12	Max.		Single case study for a patient admitted to hospital where RT-PCR <b>serial testing</b> was undertaken. Patient had an additional positive test at day 17, but subsequently tested negative
[79]	Cheng et al. (2020)	China	21	Max.		Case study of single patient <b>serially tested</b> by RT-PCR
[7]	Hu et al. (2020)	China	12	Median	12-14 (IQR)	<b>Serial testing</b> study of patients who were first tested (qRT-PCR) when asymptomatic; this subset subsequently developed symptoms (n=5).
[42]	Kim et al. (2020)	Korea	15.5	Median	14-17 (range)	<b>Serial testing</b> of two confirmed cases via RT-PCR. Viral load highest during early phase of infection (day 3-5).
[43]	Kujawski et al. (2020)	USA	26	Max.		<b>Serial testing</b> of two confirmed cases via RT-PCR. Mild to moderate symptoms.
[80]	Lee et al. (2020)	Taiwan	20	Max.		<b>Serial testing</b> (RT-PCR) of a single patient hospitalised presenting with pneumonia
[44]	Lim et al. (2020)	South Korea	16	Max.		<b>Serial testing</b> (RT-PCR) of a single patient hospitalised presenting with pneumonia. Two clear tests day 11, virus

						detectable again up to day 16.
[81]	Ling et al. (2020)	China	9.5	Median	2-22 (range)	<b>Serial testing</b> of two confirmed cases via RT-PCR. n=66. IQR: 6-11 days, oropharyngeal sampling. Mix of adult and children.
[82]	Liu et al. (2020)	China	11	Median	7-18 range	<b>Serial testing</b> of two confirmed cases via RT-PCR. n=10. 10-13 (IQR); adults, mild, moderate, and severe cases.
[45]	Marchand-Senéca et al. (2020)	Canada	23	Max		<b>Serial testing</b> (RT-PCR) of a single patient hospitalised presenting with pneumonia.
[3]	Pan et al. (2020)	China	10	Median	8-12 range	<b>Serial testing</b> (RT-PCR) of two patients hospitalised. Viral loads peaked days 5-6 post-onset.
[83]	Qu et al. (2020)	China	22	Max		<b>Serial testing</b> (RT-PCR) of a single patient hospitalised
[46]	Tan et al. (2020)	Vietnam	16	Max		<b>Serial testing</b> (RT-PCR) of a single patient hospitalised; throat sample.
[47]	Thevarajan et al. (2020)	Australia	7	Max		<b>Serial testing</b> (RT-PCR) of a single patient hospitalised; throat sample. Highest viral load on first test at day 4 in nasopharyngeal; day 6 for sputum.
[69]	Xing et al. (2020)	China	14	Median		<b>Serial testing</b> (RT-PCR) of a three (children) patients hospitalised. Mild-moderate infecting. Positive viral samples from faeces up to 4 weeks post-symptoms.
[52]	Young et al. (2020)	Singapore	12.5	Median		<b>Serial testing</b> (RT-PCR) of 18 patients hospitalised. Adults. Viral load peaked over testing series at day 4 since onset.
[84]	Yuan et al. (2020)	China	6	Median	4-10 (IQR)	<b>Serial testing</b> (RT-PCR) of 25 patients hospitalised. Children and adults. "Non-severe" cases.
[74]	Zhou et al. (2020)	China	20	Median	16-23 IQR	<b>Serial testing</b> (RT-PCR) of 191 patients hospitalised in two hospitals. Adults. 54 died. Survivors (n=137); Median (IQR) 20.0 days (17.0–24.0); Non-survivors

						(n=54); Median (IQR) 18.5 days (15.0–22.0); Shedding continued until death. Inferred shedding period; 8–37 days.
[85]	Chen J. et al. (2020)	China	11	Median	10–12 (95%CI)	<b>Serial testing</b> (RT-PCR) of 242 patients hospitalised. Adults. 90% mild/asymptomatic; 10% severe/critical.
[60]	Fang et al. (2020)	China	15.7	Mean	6.7 (sd)	<b>Serial testing</b> (RT-PCR) of 24 non-ICU patients hospitalised. Adults. Nasal samples.
[60]	Fang et al. (2020)	China	22.3	Mean	3.6 (sd)	<b>Serial testing</b> (RT-PCR) of 8 ICU patients hospitalised. Adults. Nasal samples.
[57]	Hill et al. (2020)	Scotland	9	Max.		<b>Serial testing</b> (RT-PCR) of a single patient (adult) hospitalised; nasal sample [throat sample: 6 days]. Mild.
[86]	Le et al. (2020)	Vietnam	12	Max.		<b>Serial testing</b> (RT-PCR) of a single patient (infant) hospitalised. Mild.
[58]	Liu et al. (2020)	China	10	Max.		<b>Serial testing</b> (RT-PCR) of patients hospitalised. Adults. Mixed Mild/severe cases. N=76. 90% “early viral clearance” within 10days
[87]	Qiu et al. (2020)	China	10	Mean	7–22 range	<b>Serial testing</b> (RT-PCR) of patients hospitalised. Children. N=36. Mild and moderate cases.
[59]	To et al. (2020)	Hong Kong	25	Max.		<b>Serial testing</b> (RT-PCR) of patients hospitalised. N=7. Seven patients reported viral detection >20 days; viral load peaked during first week post-onset of symptoms.
[88]	Wu et al.	China	16.1	Mean	6.7 (sd)	<b>Serial testing</b> (RT-PCR) of patients hospitalised. Adults. N=74. Severe and non-severe cases.
<b>Tracking studies</b>						
[31]	Tindale et al. (2020)	Singapore	18	Median	9–33 range	Time from onset to discharge; range 9–33; n=53

[35,36]	Kraemer et al. (2020a); [later published as: Xu et al. 2020]	Various	19	Median	3-37 range	Time from onset to discharge; Range: 3-37; n=70
[34]	Linton et al. (2020)	Wuhan, China	13	Median	6-41 range	Time from onset to death; range 6-41
[35,36]	Kraemer et al. (2020b)	Japan and China	19.25	Mean	12-24 range	Time from onset to death; n=4
[49,50]	Wölfel et al. (2020)	Germany	3-8 days	absolute	3-8 range	Tracked infection in mild cases in Germany, undertaking viral isolation studies to assess active replication across a number of samples sites (upper respiratory tract, blood, urine, faeces) over the duration of infection. 5% isolation success was achieved up to 9.78 (95% CI: 8.45-21.78) days post onset; n=9

review only

**Table 4:** Reported infectious period (IP) for symptomatic cases (T3+T5 parameter) from virological studies where serial diagnostic tests were undertaken to infer IP [exposure to  $\geq 2$  neg. tests]; tracking studies where IP is inferred from patient histories from onset to recovery or death; modelling studies where IP is reported as a prior (assumed parameter value) or an posterior estimate.

No.	Study	Location	Parameter (days)	Central tendency reported	Variation (days; inclus.)	Comment
<b>Tracking studies</b>						
[29]	He et al. (2020)	Vietnam, Malaysia, Japan, China, Taiwan, USA, Singapore	9.3 days	Mean	7.8-10 (95%CI*)	The paper reported on 77 infector-infectee pairs which were sequential/serially tested, using publicly available data. Viral dynamics (Guangzhou, China; N=94) interpreted by the authors suggested an infectious period starting 2.3 (95% CI, 0.8–3.0 days) days prior to symptoms, peaking 0.7 days (95% CI, –0.2–2.0 days), continuing up to 7 days from onset. * CI from pre-symptom infectious period only.
[8]	Ma et al. (2020)	Various	~5 days	Median	Range 0-24	The authors estimated the infectious period as latent minus the serial interval, using a dataset of 1155 cases. Range 0-24; IQR: 2-9; calculated from data presented within the paper.
<b>Modelling studies</b>						
[27]	Li et al. (2020)	China	3.45 days [posterior estimated from model for documented cases]	median	95%CI for the mean: 3.19, 3.72	Mathematical model. Priors for <u>mean</u> documented infectious period was a flat [uniform] distribution 2-5. 'Documented' cases were defined as those severe enough to be confirmed. This corraling of the infectious period relative to other

						studies should take into account that the distribution is used for the central tendency, not the whole distribution.
[26,39]	Tuite et al. (a, b) (2020)	Canada	6-6.5 days [prior; fixed parameter within a deterministic model]	Fixed parameter		Mathematical model [deterministic], with a fixed parameter estimate of 6.5 days (a) and 6 days (b), respectively. Important to note that duration for 'mild' was equal to severe cases.
[89]	Lourenco et al. (2020)	UK	~3-5 days [posterior; approximate depending on scenario tested]	mean	95%ci of 3-6 days	Mathematical model. The prior used was given a Gaussian distribution (normal curve); mean 4.5; SD 1; approximate 95%ci of 3-6 days. The reported posterior of this parameter was presented graphically and depended on R0 and proportion at risk. Depending on the scenarios tested, mean duration of infectiousness appeared to vary from 3-5 days.
[37]	Zhu et al. (2020)	Wuhan, China	12.5 days [posterior estimated from model]	Mean	11.4 variance	Mathematical model. The parameter was estimated using a Weibull distribution. The prior for this parameter was 10 days. The posterior variance around the mean was 11.4, and therefore the distribution had a long tail. This study was a modelling [SEIR extended model].
[15]	Davies et al. (b) (2020)	UK	7 days [Prior]	Mean		Model with asymptomatic infection compartment. Modelled with a

						gamma distribution, beta 1.4; alpha 5. Despite, the subclinical aspect of this parameter, it could be considered analogous to total infectious period without intervention.
[14]	Davies et al. (b) (2020)	UK	5 days [Prior]	Mean		Model with asymptomatic infection compartment. Modelled with a gamma distribution, k=4. Authors: "Assumed to be the same duration as total infectious period for clinical cases, including preclinical transmission"
[38]	Piccolomini and Zama (2020)	Italy	20 days [Prior]	Fixed		Parameter estimate assumed for the infectious period within an SEIRD model, fitted to data from the epidemic in Italy.

# Supplementary material 1

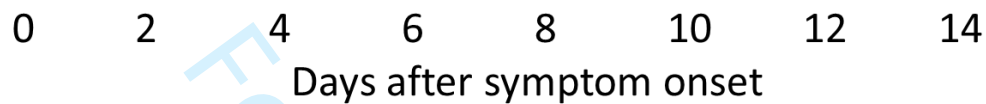

**Figure S1:** Conceptual model of the key temporal parameters impacting COVID-19 infection progression over time. T1: Latent period; T2: Asymptomatic infectious period; T3: Pre-symptomatic infectious period; T4: Symptom onset to diagnosis [self-isolation] or hospitalisation; T5: Symptom onset to removed [death or recovery]

**Figure S2:** Cumulative infectiousness (% of total infectiousness) based on infector-infectee pair data in the paper by Cheng et al. 2020. The accumulation curve is based on a gamma density function, coupled with a probability function to capture the maximal probability if exposed to a primary case.

Positive culture

Negative culture

**Figure S3:** Timeline for positive culture results of SARS-COV2 from throat, sputum and stool samples; Yellow line = Throat swabs; Orange line = Sputum samples; Blue line = Stool samples; Adapted from Wölfel et al.[50].

## Preferred Reporting Items for Systematic reviews and Meta-Analyses extension for Scoping Reviews (PRISMA-ScR) Checklist

SECTION	ITEM	PRISMA-ScR CHECKLIST ITEM	REPORTED ON PAGE #
<b>TITLE</b>			
Title	1	Identify the report as a scoping review.	1
<b>ABSTRACT</b>			
Structured summary	2	Provide a structured summary that includes (as applicable): background, objectives, eligibility criteria, sources of evidence, charting methods, results, and conclusions that relate to the review questions and objectives.	2
<b>INTRODUCTION</b>			
Rationale	3	Describe the rationale for the review in the context of what is already known. Explain why the review questions/objectives lend themselves to a scoping review approach.	3
Objectives	4	Provide an explicit statement of the questions and objectives being addressed with reference to their key elements (e.g., population or participants, concepts, and context) or other relevant key elements used to conceptualize the review questions and/or objectives.	3
<b>METHODS</b>			
Protocol and registration	5	Indicate whether a review protocol exists; state if and where it can be accessed (e.g., a Web address); and if available, provide registration information, including the registration number.	4-5
Eligibility criteria	6	Specify characteristics of the sources of evidence used as eligibility criteria (e.g., years considered, language, and publication status), and provide a rationale.	5
Information sources*	7	Describe all information sources in the search (e.g., databases with dates of coverage and contact with authors to identify additional sources), as well as the date the most recent search was executed.	4-5
Search	8	Present the full electronic search strategy for at least 1 database, including any limits used, such that it could be repeated.	4-5
Selection of sources of evidence†	9	State the process for selecting sources of evidence (i.e., screening and eligibility) included in the scoping review.	4-5
Data charting process‡	10	Describe the methods of charting data from the included sources of evidence (e.g., calibrated forms or forms that have been tested by the team before their use, and whether data charting was done independently or in duplicate) and any processes for obtaining and confirming data from investigators.	4-5
Data items	11	List and define all variables for which data were sought and any assumptions and simplifications made.	5-7
Critical appraisal of individual sources of evidence§	12	If done, provide a rationale for conducting a critical appraisal of included sources of evidence; describe the methods used and how this information was used in any data synthesis (if appropriate).	5-7
Synthesis of results	13	Describe the methods of handling and summarizing the data that were charted.	5-7

SECTION	ITEM	PRISMA-ScR CHECKLIST ITEM	REPORTED ON PAGE #
<b>RESULTS</b>			
Selection of sources of evidence	14	Give numbers of sources of evidence screened, assessed for eligibility, and included in the review, with reasons for exclusions at each stage, ideally using a flow diagram.	8, Tables 1-3
Characteristics of sources of evidence	15	For each source of evidence, present characteristics for which data were charted and provide the citations.	Tables 1-3
Critical appraisal within sources of evidence	16	If done, present data on critical appraisal of included sources of evidence (see item 12).	Tables 1-3
Results of individual sources of evidence	17	For each included source of evidence, present the relevant data that were charted that relate to the review questions and objectives.	8-13
Synthesis of results	18	Summarize and/or present the charting results as they relate to the review questions and objectives.	8-13; figures 1-5
<b>DISCUSSION</b>			
Summary of evidence	19	Summarize the main results (including an overview of concepts, themes, and types of evidence available), link to the review questions and objectives, and consider the relevance to key groups.	14-17
Limitations	20	Discuss the limitations of the scoping review process.	17-18
Conclusions	21	Provide a general interpretation of the results with respect to the review questions and objectives, as well as potential implications and/or next steps.	18
<b>FUNDING</b>			
Funding	22	Describe sources of funding for the included sources of evidence, as well as sources of funding for the scoping review. Describe the role of the funders of the scoping review.	18

JB1 = Joanna Briggs Institute; PRISMA-ScR = Preferred Reporting Items for Systematic reviews and Meta-Analyses extension for Scoping Reviews.

\* Where *sources of evidence* (see second footnote) are compiled from, such as bibliographic databases, social media platforms, and Web sites.

† A more inclusive/heterogeneous term used to account for the different types of evidence or data sources (e.g., quantitative and/or qualitative research, expert opinion, and policy documents) that may be eligible in a scoping review as opposed to only studies. This is not to be confused with *information sources* (see first footnote).

‡ The frameworks by Arksey and O'Malley (6) and Levac and colleagues (7) and the JBI guidance (4, 5) refer to the process of data extraction in a scoping review as data charting.

§ The process of systematically examining research evidence to assess its validity, results, and relevance before using it to inform a decision. This term is used for items 12 and 19 instead of "risk of bias" (which is more applicable to systematic reviews of interventions) to include and acknowledge the various sources of evidence that may be used in a scoping review (e.g., quantitative and/or qualitative research, expert opinion, and policy document).

From: Tricco AC, Lillie E, Zarin W, O'Brien KK, Colquhoun H, Levac D, et al. PRISMA Extension for Scoping Reviews (PRISMA-ScR): Checklist and Explanation. *Ann Intern Med*. 2018;169:467–473. doi: 10.7326/M18-0850.
